The backup was terminated after starting, possibly due to user intervention</p> | <p>Event Name. BackupAborted</p> <p>Event Type. Backup</p> <p>Priority. 7</p> <p>Severity. ALERT</p> |

17.5.7.2. MySQL Cluster: NDB Transporter Errors

This section lists error codes, names, and messages that are written to the cluster log in the event of transporter errors.

MySQL Cluster Log Messages

| Error Code | Error Name | Error Text |
|-------------------|---|---|
| 0x00 | TE_NO_ERROR | No error |
| 0x01 | TE_ERROR_CLOSING_SOCKET | Error found during closing of socket |
| 0x02 | TE_ERROR_IN_SELECT_BEFORE_ACCEPT | Error found before accept. The transporter will retry |
| 0x03 | TE_INVALID_MESSAGE_LENGTH | Error found in message (invalid message length) |
| 0x04 | TE_INVALID_CHECKSUM | Error found in message (checksum) |
| 0x05 | TE_COULD_NOT_CREATE_SOCKET | Error found while creating socket (can't create socket) |
| 0x06 | TE_COULD_NOT_BIND_SOCKET | Error found while binding server socket |
| 0x07 | TE_LISTEN_FAILED | Error found while listening to server socket |
| 0x08 | TE_ACCEPT_RETURN_ERROR | Error found during accept (accept return error) |
| 0x0b | TE_SHM_DISCONNECT | The remote node has disconnected |
| 0x0c | TE_SHM_IPC_STAT | Unable to check shm segment |
| 0x0d | TE_SHM_UNABLE_TO_CREATE_SEGMENT | Unable to create shm segment |
| 0x0e | TE_SHM_UNABLE_TO_ATTACH_SEGMENT | Unable to attach shm segment |
| 0x0f | TE_SHM_UNABLE_TO_REMOVE_SEGMENT | Unable to remove shm segment |
| 0x10 | TE_TOO_SMALL_SIGID | Sig ID too small |
| 0x11 | TE_TOO_LARGE_SIGID | Sig ID too large |
| 0x12 | TE_WAIT_STACK_FULL | Wait stack was full |
| 0x13 | TE_RECEIVE_BUFFER_FULL | Receive buffer was full |
| 0x14 | TE_SIGNAL_LOST_SEND_BUFFER_FULL | Send buffer was full, and trying to force send fails |
| 0x15 | TE_SIGNAL_LOST | Send failed for unknown reason (signal lost) |

| Error Code | Error Name | Error Text |
|------------|--|---|
| 0x16 | TE_SEND_BUFFER_FULL | The send buffer was full, but sleeping for a while solved |
| 0x0017 | TE_SCI_LINK_ERROR | There is no link from this node to the switch |
| 0x18 | TE_SCI_UNABLE_TO_START_SEQUENCE | Could not start a sequence, because system resources are exumed or no sequence has been created |
| 0x19 | TE_SCI_UNABLE_TO_REMOVE_SEQUENCE | Could not remove a sequence |
| 0x1a | TE_SCI_UNABLE_TO_CREATE_SEQUENCE | Could not create a sequence, because system resources are exempted. Must reboot |
| 0x1b | TE_SCI_UNRECOVERABLE_DATA_TFX_ERROR | Tried to send data on redundant link but failed |
| 0x1c | TE_SCI_CANNOT_INIT_LOCALSEGMENT | Cannot initialize local segment |
| 0x1d | TE_SCI_CANNOT_MAP_REMOTESEGMENT | Cannot map remote segment |
| 0x1e | TE_SCI_UNABLE_TO_UNMAP_SEGMENT | Cannot free the resources used by this segment (step 1) |
| 0x1f | TE_SCI_UNABLE_TO_REMOVE_SEGMENT | Cannot free the resources used by this segment (step 2) |
| 0x20 | TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT | Cannot disconnect from a remote segment |
| 0x21 | TE_SHM_IPC_PERMANENT | Shm ipc Permanent error |
| 0x22 | TE_SCI_UNABLE_TO_CLOSE_CHANNEL | Unable to close the sci channel and the resources allocated |

17.5.8. MySQL Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see [Section 17.5.10.13, “The `ndbinfo nodes` Table”](#), for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
 1. Finish all single user mode transactions
 2. Issue the `EXIT SINGLE USER MODE` command
 3. Restart the cluster's data nodes
- Method 2:

Restart database nodes prior to entering single user mode.

17.5.9. Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS`, `SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

See [Section 13.7.5.16, “`SHOW ENGINE Syntax`”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 13.7.5.17, “SHOW ENGINES Syntax”](#), for more detailed information.

Note

In MySQL 5.1 and later, this statement does not support a [LIKE \[1111\]](#) clause. However, you can use [LIKE \[1111\]](#) to filter queries against the [INFORMATION_SCHEMA.ENGINES](#), as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a [LIKE \[1111\]](#) clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
+-----+
| support |
+-----+
| ENABLED |
+-----+
```

See [Section 20.6, “The INFORMATION_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ndb_autoincrement_prefetch_sz | 32 |
| ndb_cache_check_time | 0 |
| ndb_extra_logging | 0 |
| ndb_force_send | ON |
| ndb_index_stat_cache_entries | 32 |
| ndb_index_stat_enable | OFF |
| ndb_index_stat_update_freq | 20 |
| ndb_report_thresh_binlog_epoch_slip | 3 |
| ndb_report_thresh_binlog_mem_usage | 10 |
| ndb_use_copying_alter_table | OFF |
| ndb_use_exact_count | ON |
| ndb_use_transactions | ON |
+-----+-----+
```

See [Section 5.1.4, “Server System Variables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%'`

This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
```

```
-> WHERE VARIABLE_NAME LIKE 'NDB%';
```

| VARIABLE_NAME | VARIABLE_VALUE |
|-------------------------------------|----------------|
| NDB_AUTOINCREMENT_PREFETCH_SZ | 32 |
| NDB_CACHE_CHECK_TIME | 0 |
| NDB_EXTRA_LOGGING | 0 |
| NDB_FORCE_SEND | ON |
| NDB_INDEX_STAT_CACHE_ENTRIES | 32 |
| NDB_INDEX_STAT_ENABLE | OFF |
| NDB_INDEX_STAT_UPDATE_FREQ | 20 |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3 |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE | 10 |
| NDB_USE_COPYING_ALTER_TABLE | OFF |
| NDB_USE_EXACT_COUNT | ON |
| NDB_USE_TRANSACTIONS | ON |

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
-> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME = 'ndb_force_send';
```

| VARIABLE_VALUE |
|----------------|
| ON |

See [Section 20.9, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”](#), and [Section 5.1.4, “Server System Variables”](#), for more information.

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

| Variable_name | Value |
|--------------------------|---------------|
| Ndb_cluster_node_id | 10 |
| Ndb_config_from_host | 192.168.0.103 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_data_nodes | 4 |

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
```

| Variable_name | Value |
|--------------------------|-------|
| Ndb_cluster_node_id | 0 |
| Ndb_config_from_host | |
| Ndb_config_from_port | 0 |
| Ndb_number_of_data_nodes | 0 |

See also [Section 13.7.5.36, “SHOW STATUS Syntax”](#).

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB %';`

This statement provides similar output to the `SHOW` command discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the `SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See [Section 20.8, “The `INFORMATION_SCHEMA.GLOBAL_STATUS` and `SESSION_STATUS` Tables”](#), for more information.

You can also query the tables in the `ndbinfo` information database for real-time data about many MySQL Cluster operations. See [Section 17.5.10, “The `ndbinfo` MySQL Cluster Information Database”](#).

17.5.10. The `ndbinfo` MySQL Cluster Information Database

`ndbinfo` is a database storing containing information specific to MySQL Cluster.

This database contains a number of tables, each providing a different sort of data about MySQL Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

`ndbinfo` is included with MySQL Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the `Name` column and `ACTIVE` in the `Status` column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+-----+
| Name                               | Status | Type                | Library | License |
+-----+-----+-----+-----+-----+-----+
| binlog                             | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| mysql_native_password              | ACTIVE | AUTHENTICATION     | NULL   | GPL     |
| mysql_old_password                 | ACTIVE | AUTHENTICATION     | NULL   | GPL     |
| CSV                                 | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| MEMORY                             | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| MRG_MYISAM                         | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| MyISAM                             | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| PERFORMANCE_SCHEMA                | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| BLACKHOLE                          | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| ARCHIVE                            | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| ndbcluster                         | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| ndbinfo                           | ACTIVE | STORAGE ENGINE   | NULL   | GPL   |
| ndb_transid_mysql_connection_map   | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| InnoDB                             | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
| INNODB_TRX                        | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| INNODB_LOCKS                      | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| INNODB_LOCK_WAITS                  | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| INNODB_CMP                         | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| INNODB_CMP_RESET                   | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| INNODB_CMPMEM                     | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| INNODB_CMPMEM_RESET               | ACTIVE | INFORMATION SCHEMA | NULL   | GPL     |
| partition                          | ACTIVE | STORAGE ENGINE     | NULL   | GPL     |
+-----+-----+-----+-----+-----+-----+
22 rows in set (0.00 sec)
```

You can also do this by checking the output of `SHOW ENGINES` for a line including `ndbinfo` in the `Engine` column and `YES` in the `Support` column, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
***** 1. row *****
      Engine: ndbcluster
      Support: YES
```

```

    Savepoints: NO

```

```
10 rows in set (0.00 sec)
```

If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| ndbinfo |
| test |
+-----+
4 rows in set (0.00 sec)
```

If the `mysqld` process was not started with the `--ndbcluster` [2142] option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to a MySQL Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal `NDB` tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+-----+
| Tables_in_ndbinfo |
+-----+
| blocks |
| cluster_operations |
| cluster_transactions |
| config_params |
| counters |
| diskpagebuffer |
| logbuffers |
| logspaces |
| memoryusage |
| nodes |
| resources |
| server_operations |
| server_transactions |
| threadblocks |
| threadstat |
| transporters |
+-----+
16 rows in set (0.04 sec)
```

The `cluster_operations`, `cluster_transactions`, `server_operations`, `server_transactions`, `threadblocks`, and `threadstat` tables were added in MySQL Cluster NDB 7.2.2.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;
+-----+-----+-----+-----+
| node_id | DATA_MEMORY | used | max |
+-----+-----+-----+-----+
|      1 | DATA_MEMORY | 3230 | 6408 |
|      2 | DATA_MEMORY | 3230 | 6408 |
|      1 | INDEX_MEMORY | 16   | 12832 |
|      2 | INDEX_MEMORY | 16   | 12832 |
+-----+-----+-----+-----+
4 rows in set (0.37 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
> FROM memoryusage
> WHERE DATA_MEMORY = 'DATA_MEMORY';
+-----+
| Data Memory Used, All Nodes |
+-----+
|                          6460 |
+-----+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
> FROM memoryusage
> WHERE DATA_MEMORY = 'INDEX_MEMORY';
+-----+
| Total IndexMemory Available |
+-----+
|                          25664 |
+-----+
1 row in set (0.33 sec)
```

`ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+
| node_id | uptime | status | start_phase |
+-----+-----+-----+-----+
|      1 | 13602 | STARTED | 0 |
|      2 | 16    | STARTED | 0 |
+-----+-----+-----+-----+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

`mysqldump` ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` [314] or `--all-databases` [313] option.

MySQL Cluster also maintains tables in the `INFORMATION_SCHEMA` information database, including the `FILES` table which contains information about files used for MySQL Cluster Disk Data storage. For more information, see [Section 20.29, “INFORMATION_SCHEMA Tables for MySQL Cluster”](#).

17.5.10.1. The `ndbinfo` `arbiterator_validity_detail` Table

The `arbitrator_validity_detail` table shows the view that each data node in the cluster of the arbitrator. It is a subset of the `membership` table.

The following table provides information about the columns in the `arbitrator_validity_detail` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|----------------------------|------------------------|--|
| <code>node_id</code> | integer | This node's node ID |
| <code>arbitrator</code> | integer | Node ID of arbitrator |
| <code>arb_ticket</code> | string | Internal identifier used to track arbitration |
| <code>arb_connected</code> | Yes or No | Whether this node is connected to the arbitrator |
| <code>arb_state</code> | Enumeration (see text) | Arbitration state |

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the `arbitrator`.

Like the `membership` and `arbitrator_validity_summary` tables, this table was added in MySQL Cluster NDB 7.2.10.

17.5.10.2. The `ndbinfo` `arbitrator_validity_summary` Table

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The following table provides information about the columns in the `arbitrator_validity_detail` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|------------------------------|-----------|---|
| <code>arbitrator</code> | integer | Node ID of arbitrator |
| <code>arb_ticket</code> | string | Internal identifier used to track arbitration |
| <code>arb_connected</code> | Yes or No | Whether this arbitrator is connected to the cluster |
| <code>consensus_count</code> | integer | Number of data nodes that see this node as arbitrator |

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

Like the `membership` and `arbitrator_validity_detail` tables, this table was added in MySQL Cluster NDB 7.2.10.

17.5.10.3. The `ndbinfo` `blocks` Table

The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see [NDB Kernel Blocks](#)). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the `blocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|---------------------------|---------|--------------|
| <code>block_number</code> | integer | Block number |
| <code>block_name</code> | string | Block name |

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different MySQL Cluster releases.

17.5.10.4. The `ndbinfo` `cluster_operations` Table

The `cluster_operations` table provides a per-operation (stateful primary key op) view of all activity in the MySQL Cluster from the point of view of the local data management (LQH) blocks (see [The DBLQH Block](#)).

The following table provides information about the columns in the `cluster_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|--------------------------------|---------|--|
| <code>node_id</code> | integer | Node ID of reporting LQH block |
| <code>block_instance</code> | integer | LQH block instance |
| <code>transid</code> | integer | Transaction ID |
| <code>operation_type</code> | string | Operation type (see text for possible values) |
| <code>state</code> | string | Operation state (see text for possible values) |
| <code>tableid</code> | integer | Table ID |
| <code>fragmentid</code> | integer | Fragment ID |
| <code>client_node_id</code> | integer | Client node ID |
| <code>client_block_ref</code> | integer | Client block reference |
| <code>tc_node_id</code> | integer | Transaction coordinator node ID |
| <code>tc_block_no</code> | integer | Transaction coordinator block number |
| <code>tc_block_instance</code> | integer | Transaction coordinator block instance |

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`,

`COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` [2159] enabled, you can view this list of states by selecting from the `ndb $dbldqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` [2207] (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.2.2.

17.5.10.5. The `ndbinfo cluster_transactions` Table

The `cluster_transactions` table shows information about all ongoing transactions in a MySQL Cluster.

The following table provides information about the columns in the `cluster_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|-------------------------------------|---------|---|
| <code>node_id</code> | integer | Node ID of transaction coordinator |
| <code>block_instance</code> | integer | TC block instance |
| <code>transid</code> | integer | Transaction ID |
| <code>state</code> | string | Operation state (see text for possible values) |
| <code>count_operations</code> | integer | Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations) |
| <code>outstanding_operations</code> | integer | Operations still being executed in local data management blocks |
| <code>inactive_seconds</code> | integer | Time spent waiting for API |
| <code>client_node_id</code> | integer | Client node ID |
| <code>client_block_ref</code> | integer | Client block reference |

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`,

`CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` [2159] enabled, you can view this list of states by selecting from the `ndb$dbtbc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.2.2.

17.5.10.6. The `ndbinfo config_params` Table

The `config_params` table is a static table which provides the names and internal ID numbers of all MySQL Cluster configuration parameters.

The following table provides information about the columns in the `config_params` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|---------------------------|---------|------------------------------------|
| <code>param_number</code> | integer | The parameter's internal ID number |
| <code>param_name</code> | string | The name of the parameter |

Although this is a static table, its content can vary between MySQL Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

17.5.10.7. The `ndbinfo counters` Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|-----------------------------|---------|--|
| <code>node_id</code> | integer | The data node ID |
| <code>block_name</code> | string | Name of the associated NDB kernel block (see NDB Kernel Blocks). |
| <code>block_instance</code> | integer | Block instance |
| <code>counter_id</code> | integer | The counter's internal ID number; normally an integer between 1 and 10, inclusive. |
| <code>counter_name</code> | string | The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated. |
| <code>val</code> | integer | The counter's value |

Each counter is associated with a particular NDB kernel block. Prior to MySQL Cluster NDB 7.2.0, this was limited to either the `DBLQH` kernel block or the `DBTC` kernel block.

The `OPERATIONS` counter is associated with the `DBLQH` (local query handler) kernel block (see [The DBLQH Block](#)).

The `ATTRINFO`, `TRANSACTIONS`, `COMMITTS`, `READS`, `SIMPLE_READS`, `WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the DBTC (transaction co-ordinator) kernel block (see [The DBTC Block](#)).

MySQL Cluster NDB 7.2.0, as part of its implementation of distributed pushed-down joins, adds the `LOCAL_TABLE_SCANS_SENT`, `READS_RECEIVED`, `PRUNED_RANGE_SCANS_RECEIVED`, `RANGE_SCANS_RECEIVED`, `LOCAL_READS_SENT`, `CONST_PRUNED_RANGE_SCANS_RECEIVED`, `LOCAL_RANGE_SCANS_SENT`, `REMOTE_READS_SENT`, `REMOTE_RANGE_SCANS_SENT`, `READS_NOT_FOUND`, `SCAN_BATCHES_RETURNED`, `TABLE_SCANS_RECEIVED`, and `SCAN_ROWS_RETURNED` counters. These counters are associated with the `DBSPJ` (select push-down join) kernel block (see [The DBSPJ Block](#)).

A number of counters increasing the visibility of transporter overload and send buffer sizing when troubleshooting such issues were added in MySQL Cluster NDB 7.2.10. (Bug #15935206) For each LQH instance, there is one instance of each counter in the following list:

- `LQHKEY_OVERLOAD`: Number of primary key requests rejected at the LQH block instance due to transporter overload
- `LQHKEY_OVERLOAD_TC`: Count of instances of `LQHKEY_OVERLOAD` where the TC node transporter was overloaded
- `LQHKEY_OVERLOAD_READER`: Count of instances of `LQHKEY_OVERLOAD` where the API reader (reads only) node was overloaded.
- `LQHKEY_OVERLOAD_NODE_PEER`: Count of instances of `LQHKEY_OVERLOAD` where the next backup data node (writes only) was overloaded
- `LQHKEY_OVERLOAD_SUBSCRIBER`: Count of instances of `LQHKEY_OVERLOAD` where a event subscriber (writes only) was overloaded.
- `LQHSCAN_SLOWDOWNS`: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

17.5.10.8. The `ndbinfo` `diskpagebuffer` Table

The `diskpagebuffer` table provides statistics about disk page buffer usage by MySQL Cluster Disk Data tables.

The following table provides information about the columns in the `diskpagebuffer` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|--|---------|---|
| <code>node_id</code> | integer | The data node ID |
| <code>block_instance</code> | integer | Block instance |
| <code>pages_written</code> | integer | Number of pages written to disk. |
| <code>pages_written_lcp</code> | integer | Number of pages written by local checkpoints. |
| <code>pages_read</code> | integer | Number of pages read from disk |
| <code>log_waits</code> | integer | Number of page writes waiting for log to be written to disk |
| <code>page_requests_direct_return</code> | integer | Number of requests for pages that were available in buffer |

| Column Name | Type | Remarks |
|---------------------------------------|---------|--|
| <code>page_requests_wait_queue</code> | integer | Number of requests that had to wait for pages to become available in buffer |
| <code>page_requests_wait_io</code> | integer | Number of requests that had to be read from pages on disk (pages were unavailable in buffer) |

You can use this table with MySQL Cluster Disk Data tables to determine whether `DiskPageBufferMemory` [2083] is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` [2083] to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return /
    (page_requests_direct_return + page_requests_wait_io)
  AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
+-----+-----+
| node_id | hit_ratio |
+-----+-----+
|      5 |  97.6744 |
|      6 |  97.6879 |
|      7 |  98.1776 |
|      8 |  98.1343 |
+-----+-----+
4 rows in set (0.00 sec)
```

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` [2083] needs to be increased in the `config.ini` file.

Note

A change in `DiskPageBufferMemory` [2083] requires a rolling restart of all of the cluster's data nodes before it takes effect.

17.5.10.9. The `ndbinfo logbuffers` Table

The `logbuffer` table provides information on MySQL Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

| Column Name | Type | Remarks |
|-----------------------|---------|--|
| <code>node_id</code> | integer | The ID of this data node. |
| <code>log_type</code> | string | Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> . |
| <code>log_id</code> | integer | The log ID. |
| <code>log_part</code> | integer | The log part number. |
| <code>total</code> | integer | Total space available for this log. |

| Column Name | Type | Remarks |
|-------------------|---------|-------------------------|
| <code>used</code> | integer | Space used by this log. |

17.5.10.10. The `ndbinfo logspaces` Table

This table provides information about MySQL Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

| Column Name | Type | Remarks |
|-----------------------|---------|--|
| <code>node_id</code> | integer | The ID of this data node. |
| <code>log_type</code> | string | Type of log; one of: <code>REDO</code> or <code>DD-UNDO</code> . |
| <code>log_id</code> | integer | The log ID. |
| <code>log_part</code> | integer | The log part number. |
| <code>total</code> | integer | Total space available for this log. |
| <code>used</code> | integer | Space used by this log. |

17.5.10.11. The `ndbinfo membership` Table

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The following table provides information about the columns in the `membership` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|-----------------------------------|------------------------|--|
| <code>node_id</code> | integer | This node's node ID |
| <code>group_id</code> | integer | Node group to which this node belongs |
| <code>left_node</code> | integer | Node ID of the previous node |
| <code>right_node</code> | integer | Node ID of the next node |
| <code>president</code> | integer | President's node ID |
| <code>successor</code> | integer | Node ID of successor to president |
| <code>succession_order</code> | integer | Order in which this node succeeds to presidency |
| <code>Conf_HB_order</code> | integer | - |
| <code>arbitrator</code> | integer | Node ID of arbitrator |
| <code>arb_ticket</code> | string | Internal identifier used to track arbitration |
| <code>arb_state</code> | Enumeration (see text) | Arbitration state |
| <code>arb_connected</code> | Yes or No | Whether this node is connected to the arbitrator |
| <code>connected_rank1_arbs</code> | List of node IDs | Connected arbitrators of rank 1 |
| <code>connected_rank2_arbs</code> | List of node IDs | Connected arbitrators of rank 1 |

The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

`left_node` and `right_node` are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id,left_node,right_node
-> FROM ndbinfo.membership;
```

| node_id | left_node | right_node |
|---------|-----------|------------|
| 5 | 15 | 6 |
| 6 | 5 | 7 |
| 7 | 6 | 8 |
| 8 | 7 | 12 |
| 12 | 8 | 13 |
| 13 | 12 | 14 |
| 14 | 13 | 15 |
| 15 | 14 | 5 |

8 rows in set (0.00 sec)

The designations “left” and “right” are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see [MySQL Cluster Start Phases](#)). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal MySQL Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as `1` in the order of succession, the `successor` node should see itself as `2`, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node's `arbitorator`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an `ArbitrationRank` [2037] equal to 1, or to 2, respectively.

Note

Both management nodes and API nodes are eligible to become arbitrators.

Like the `arbitrator_validity_detail` and `arbitrator_validity_summary` tables, this table was added in MySQL Cluster NDB 7.2.10.

17.5.10.12. The `ndbinfo memoryusage` Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The following table provides information about the columns in the `memoryusage` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|--------------------------|---------|---|
| <code>node_id</code> | integer | The node ID of this data node. |
| <code>memory_type</code> | string | One of <code>DATA_MEMORY</code> or <code>INDEX_MEMORY</code> . |
| <code>used</code> | integer | Number of bytes currently used for data memory or index memory by this data node. |
| <code>used_pages</code> | integer | Number of pages currently used for data memory or index memory by this data node; see text. |
| <code>total</code> | integer | Total number of bytes of data memory or index memory available for this data node; see text. |
| <code>total_pages</code> | integer | Total number of memory pages available for data memory or index memory on this data node; see text. |

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 1 and 2, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
```

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
> FROM ndbinfo.memoryusage;
+-----+-----+-----+
| node_id | memory_type | total |
+-----+-----+-----+
| 1 | Data memory | 104857600 |
| 1 | Index memory | 105119744 |
| 2 | Data memory | 104857600 |
| 2 | Index memory | 105119744 |
+-----+-----+-----+
4 rows in set (0.30 sec)
```

In this case, the `total` column values for index memory are slightly higher than the value set of `IndexMemory` [2044] due to internal rounding.

For the `used_pages` and `total_pages` columns, resources are measured in pages, which are 32K in size for `DataMemory` [2043] and 8K for `IndexMemory` [2044].

17.5.10.13. The `ndbinfo nodes` Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|--------------------------------|---------|---|
| <code>node_id</code> | integer | The data node's unique node ID in the cluster. |
| <code>uptime</code> | integer | Time since the node was last started, in seconds. |
| <code>status</code> | string | Current status of the data node; see text for possible values. |
| <code>start_phase</code> | integer | If the data node is starting, the current start phase. |
| <code>config_generation</code> | integer | The version of the cluster configuration file in use on this data node. |

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtid` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a non-zero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see Section 17.5.8, “MySQL Cluster Single User Mode”). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see Section 17.5.2, “Commands in the MySQL Cluster Management Client”). If the node is not currently starting, then this column shows 0. For a listing of MySQL Cluster start phases with descriptions, see Section 17.5.1, “Summary of MySQL Cluster Start Phases”.

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
```

```

+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
| 1 | 10462 | STARTED | 0 | 6 |
| 2 | 10460 | STARTED | 0 | 6 |
| 3 | 10457 | STARTED | 0 | 5 |
| 4 | 10455 | STARTED | 0 | 6 |
+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)

```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have a MySQL Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```

mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
| 1 | 11776 | STARTED | 0 | 6 |
| 2 | 11774 | STARTED | 0 | 6 |
| 3 | 11771 | STARTED | 0 | 6 |
| 4 | 11769 | STARTED | 0 | 6 |
+-----+-----+-----+-----+-----+
4 rows in set (0.04 sec)

```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```

ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.

mysql> SELECT * FROM nodes;
+-----+-----+-----+-----+-----+
| node_id | uptime | status | start_phase | config_generation |
+-----+-----+-----+-----+-----+
| 1 | 11807 | STARTED | 0 | 6 |
| 3 | 11802 | STARTED | 0 | 6 |
| 4 | 11800 | STARTED | 0 | 6 |
+-----+-----+-----+-----+-----+
3 rows in set (0.02 sec)

```

17.5.10.14. The `ndbinfo resources` Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The following table provides information about the columns in the `resources` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|----------------------------|---------|--|
| <code>node_id</code> | integer | The unique node ID of this data node. |
| <code>resource_name</code> | string | Name of the resource; see text. |
| <code>reserved</code> | integer | The amount reserved for this resource. |
| <code>used</code> | integer | The amount actually used by this resource. |

| Column Name | Type | Remarks |
|------------------|---------|--|
| <code>max</code> | integer | The maximum amount of this resource used, since the node was last started. |

The `resource_name` can be one of `RESERVED`, `DISK_OPERATIONS`, `DISK_RECORDS`, `DATA_MEMORY`, `JOBBUFFER`, `FILE_BUFFERS`, or `TRANSPORTER_BUFFERS`.

17.5.10.15. The `ndbinfo server_operations` Table

The `server_operations` table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the `server_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|----------------------------------|---------|--|
| <code>mysql_connection_id</code> | integer | MySQL Server connection ID |
| <code>node_id</code> | integer | Node ID |
| <code>block_instance</code> | integer | Block instance |
| <code>transid</code> | integer | Transaction ID |
| <code>operation_type</code> | string | Operation type (see text for possible values) |
| <code>state</code> | string | Operation state (see text for possible values) |
| <code>tableid</code> | integer | Table ID |
| <code>fragmentid</code> | integer | Fragment ID |
| <code>client_node_id</code> | integer | Client node ID |
| <code>client_block_ref</code> | integer | Client block reference |
| <code>tc_node_id</code> | integer | Transaction coordinator node ID |
| <code>tc_block_no</code> | integer | Transaction coordinator block number |
| <code>tc_block_instance</code> | integer | Transaction coordinator block instance |

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`,

`WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` [2159] enabled, you can view this list of states by selecting from the `ndb $dblqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` [2207] (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.2.2.

17.5.10.16. The `ndbinfo server_transactions` Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The following table provides information about the columns in the `server_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|-------------------------------------|---------|---|
| <code>mysql_connection_id</code> | integer | MySQL Server connection ID |
| <code>node_id</code> | integer | Transaction coordinator node ID |
| <code>block_instance</code> | integer | Transaction coordinator block instance |
| <code>transid</code> | integer | Transaction ID |
| <code>state</code> | string | Operation state (see text for possible values) |
| <code>count_operations</code> | integer | Number of stateful operations in the transaction |
| <code>outstanding_operations</code> | integer | Operations still being executed by local data management layer (LQH blocks) |
| <code>inactive_seconds</code> | integer | Time spent waiting for API |
| <code>client_node_id</code> | integer | Client node ID |
| <code>client_block_ref</code> | integer | Client block reference |

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` [2159]

enabled, you can view this list of states by selecting from the `ndb$dbtcc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.2.2.

17.5.10.17. The `ndbinfo threadblocks` Table

The `threadblocks` table associates data nodes, threads, and instances of NDB kernel blocks.

The following table provides information about the columns in the `threadblocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|-----------------------------|---------|-----------------------|
| <code>node_id</code> | integer | Node ID |
| <code>thr_no</code> | integer | Thread ID |
| <code>block_name</code> | string | Block name |
| <code>block_instance</code> | integer | Block instance number |

The `block_name` is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given MySQL Cluster release, the list may vary between releases.

This table was added in MySQL Cluster NDB 7.2.2.

17.5.10.18. The `ndbinfo threadstat` Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the NDB kernel.

The following table provides information about the columns in the `threadstat` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|-----------------------------|---------|--|
| <code>node_id</code> | integer | Node ID |
| <code>thr_no</code> | integer | Thread ID |
| <code>thr_nm</code> | string | Thread name |
| <code>c_loop</code> | string | Number of loops in main loop |
| <code>c_exec</code> | string | Number of signals executed |
| <code>c_wait</code> | string | Number of times waiting for additional input |
| <code>c_l_sent_prioa</code> | integer | Number of priority A signals sent to own node |
| <code>c_l_sent_priob</code> | integer | Number of priority B signals sent to own node |
| <code>c_r_sent_prioa</code> | integer | Number of priority A signals sent to remote node |
| <code>c_r_sent_priob</code> | integer | Number of priority B signals sent to remote node |
| <code>os_tid</code> | integer | OS thread ID |
| <code>os_now</code> | integer | OS time (ms) |

| Column Name | Type | Remarks |
|---------------------------|---------|-------------------------------------|
| <code>os_ru_utime</code> | integer | OS user CPU time (μ s) |
| <code>os_ru_stime</code> | integer | OS system CPU time (μ s) |
| <code>os_ru_minflt</code> | integer | OS page reclaims (soft page faults) |
| <code>os_ru_majflt</code> | integer | OS page faults (hard page faults) |
| <code>os_ru_nvcsw</code> | integer | OS voluntary context switches |
| <code>os_ru_nivcsw</code> | integer | OS involuntary context switches |

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see [Section 19.4, "Using the Event Scheduler"](#).

This table was added in MySQL Cluster NDB 7.2.2.

17.5.10.19. The `ndbinfo transporters` Table

This table contains information about NDB transporters.

The following table provides information about the columns in the `transporters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

| Column Name | Type | Remarks |
|-----------------------------|---------|---|
| <code>node_id</code> | integer | This data node's unique node ID in the cluster. |
| <code>remote_node_id</code> | integer | The remote data node's node ID. |
| <code>status</code> | string | Status of the connection. |
| <code>remote_address</code> | string | Name or IP address of the remote host |
| <code>bytes_sent</code> | integer | Number of bytes sent using this connection |
| <code>bytes_received</code> | | Number of bytes received using this connection |
| <code>connect_count</code> | | Number of times connection established on this transporter |
| <code>overloaded</code> | | 1 if this transporter is currently overloaded, otherwise 0 |
| <code>overload_count</code> | | Number of times this transporter has entered overload state since connecting |
| <code>slowdown</code> | | 1 if this transporter is in scan slowdown state, otherwise 0 |
| <code>slowdown_count</code> | | Number of times this transporter has entered scan slowdown state since connecting |

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, *including itself*. This information is shown

in the table's `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data nodes which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address`, `bytes_sent`, and `bytes_received` columns were added in MySQL Cluster NDB 7.2.9. The `remote_address` is the the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established; for nodes whose status is `CONNECTING` or `DISCONNECTED`, these columns always display 0.

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` columns were added in MySQL Cluster NDB 7.2.10. These counters are reset on connection, and retain their values after the remote node disconnects. Also beginning with MySQL Cluster NDB 7.2.10, the `bytes_send` and `bytes_received` counters are reset on connection as well, and so retain their values following disconnection. (Previously, the values in these columns were reset on disconnection.) (Bug #15935206)

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1      @10.100.10.1  (5.5.29-ndb-7.2.10, Nodegroup: 0, Master)
id=2      @10.100.10.2  (5.5.29-ndb-7.2.10, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10     @10.100.10.10 (5.5.29-ndb-7.2.10)

[mysqld(API)]   2 node(s)
id=20     @10.100.10.20 (5.5.29-ndb-7.2.10)
id=21     @10.100.10.21 (5.5.29-ndb-7.2.10)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
+-----+-----+-----+
| node_id | remote_node_id | status |
+-----+-----+-----+
| 1 | 1 | CONNECTED |
| 1 | 2 | CONNECTED |
| 1 | 10 | CONNECTED |
| 1 | 20 | CONNECTED |
| 1 | 21 | CONNECTED |
| 2 | 1 | CONNECTED |
| 2 | 2 | CONNECTED |
| 2 | 10 | CONNECTED |
| 2 | 20 | CONNECTED |
| 2 | 21 | CONNECTED |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command `2 STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for

each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
-> FROM ndbinfo.transporters;
+-----+-----+-----+
| node_id | remote_node_id | status      |
+-----+-----+-----+
| 1       | 1              | CONNECTED  |
| 1       | 2              | CONNECTING  |
| 1       | 10             | CONNECTED  |
| 1       | 20             | CONNECTED  |
| 1       | 21             | CONNECTED  |
+-----+-----+-----+
5 rows in set (0.02 sec)
```

17.5.11. MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics covered in this section include the following:

- MySQL Cluster and network security issues
- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to MySQL Cluster

17.5.11.1. MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using “free slots” created by empty `[mysqld]` or `[api]` sections in the `config.ini` file

This means that, if there are any empty `[mysqld]` or `[api]` sections in the `config.ini` file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See [Section 17.5.11.2, “MySQL Cluster and MySQL Privileges”](#), for more information about this and related issues.)

**Note**

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available elsewhere in this chapter [2091] about the `HostName` parameter. Also see Section 17.3.1, “Quick Test Setup of MySQL Cluster”, for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of a MySQL Cluster setup using such a physically segregated network here:

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a *network-based firewall*.

This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside

—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See [Section 6.1.3, “Making MySQL Secure Against Attackers”](#), for a description of techniques you can use to secure MySQL servers.

- Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for MySQL Cluster is illustrated here:

Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that

are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

| Type of Node to be Accessed | Traffic to Permit |
|------------------------------|--|
| SQL or API node | <ul style="list-style-type: none"> • It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from within the network in which the cluster resides and is on the port that your application is using. |
| Data node or Management node | <ul style="list-style-type: none"> • It originates from the IP address of a management or data node (using any TCP or UDP port). • It originates from the IP address of an SQL or API node. |

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

Note

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is *not* recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

17.5.11.2. MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (`SELECT` [697] privilege, `UPDATE` [697] privilege, `DELETE` [696] privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. In MySQL Cluster `NDB 7.2` (and later), you can enable automatic distribution of MySQL users and privileges across MySQL Cluster SQL nodes; see [Section 17.5.14, “Distributed MySQL Privileges for MySQL Cluster”](#), for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the MySQL Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.
- There is no firewall, or the firewall fails to protect against access to the MySQL Cluster from hosts external to the network.
- The host name or IP address of the MySQL Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster` [2142] `--ndb-connectstring=management_host` [2141] and access this MySQL Cluster. Using the MySQL `root` account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all `NDB` databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all `NDB` tables in a given database
- Run any legal MySQL statements on any of the discovered tables, such as:
 - `SELECT * FROM some_table` to read all the data from any table
 - `DELETE FROM some_table` to delete all the data from a table
 - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
 - `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than `NDB`, and so not visible to a “rogue” SQL node.

A user who can log in as `root` can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the `root` accounts on different MySQL Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

Important

Never leave the MySQL root account password empty. This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

Prior to MySQL Cluster `NDB` 7.2, you should never convert the system tables in the `mysql` database to use the `NDB` storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect `mysql` tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than `MyISAM`.* This is a consequence of various MySQL Server internals. Beginning with MySQL Cluster `NDB` 7.2, you can use a stored procedure provided for this purpose (see [Section 17.5.14, “Distributed MySQL Privileges for MySQL Cluster”](#)), but you are strongly advised not to attempt convert the system tables manually.

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

Summary. The most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.
2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the MySQL Cluster distribution.
3. Once a MySQL user is granted privileges on an `NDB` table from one SQL node in a MySQL Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

17.5.11.3. MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql`

system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the system user `mysql` by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root      10467  0.0  0.1  3616  1380 pts/3    S      11:53   0:00 \
  /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql     10512  0.2  2.5  58528 26636 pts/3    Sl     11:53   0:00 \
  /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
  --datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
  --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
  --log-error=/usr/local/mysql/var/mothra.err
jon       10579  0.0  0.0   2736   688 pts/0    S+    11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` [439] option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` [466] on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see [Section 17.5.11.2, “MySQL Cluster and MySQL Privileges”](#)), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root

mysql> UPDATE mysql.user
  ->   SET Password=PASSWORD('secure_password')
  ->   WHERE User='root';

mysql> DELETE FROM mysql.user
  ->   WHERE User='';

mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting *all* MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

Note

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See [Section 17.4, “MySQL Cluster Programs”](#), for more information about these utilities.

17.5.12. MySQL Cluster Disk Data Tables

It is possible to store the nonindexed columns of `NDB` tables on disk, rather than in RAM.

As part of implementing MySQL Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronizing a starting node with very large data sets. For more information, see the paper [Recovery Principles of MySQL Cluster 5.1](#), by MySQL Cluster developers Mikael Ronström and Jonas Orelund.

MySQL Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see [MySQL Cluster Disk Data configuration parameters](#) and [MySQL Cluster Disk Data storage and GCP Stop errors](#)

The performance of a MySQL Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see [Section 17.5.12.2, “Using Symbolic Links with Disk Data Objects”](#).

17.5.12.1. MySQL Cluster Disk Data Objects

MySQL Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- *Tablespaces* act as containers for other Disk Data objects.
- *Undo log files* undo information required for rolling back transactions.
- One or more undo log files are assigned to a *log file group*, which is then assigned to a tablespace.
- *Data files* store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the MySQL Cluster `config.ini` file, and where `node_id` is the data node's node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

MySQL Cluster tablespaces and log file groups are not implemented as files.

Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named `ddl`.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes), the basic steps for creating a MySQL Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

**Note**

Undo log files are necessary only for Disk Data tables; they are not used for [NDBCLUSTER](#) tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the `mysql` client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.log` and `undo_2.log`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.log` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add `undo_2.log` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognisable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` clause. In MySQL Cluster NDB 7.2, the only permitted values for this clause are `NDBCLUSTER` and `NDB`.

**Important**

There can exist at most one log file group in the same MySQL Cluster at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir [2042]` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.
- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.

- For more information about the `CREATE LOGFILE GROUP` statement, see [Section 13.1.14](#), “`CREATE LOGFILE GROUP Syntax`”. For more information about `ALTER LOGFILE GROUP`, see [Section 13.1.3](#), “`ALTER LOGFILE GROUP Syntax`”.
2. Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.
 - When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` [2042] of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.
 - All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL MySQL Cluster NDB 7.2, the only permitted values for this clause are `NDBCLUSTER` and `NDB`.
 - For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see [Section 13.1.18](#), “`CREATE TABLESPACE Syntax`”, and [Section 13.1.8](#), “`ALTER TABLESPACE Syntax`”.
3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
```

```

first_name VARCHAR(50) NOT NULL,
dob DATE NOT NULL,
joined DATE NOT NULL,
INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;

```

The `TABLESPACE ... STORAGE DISK` option tells the `NDBCLUSTER` storage engine to use tablespace `ts_1` for disk data storage.

Note

It is also possible to specify whether an individual column is stored on disk or in memory by using a `STORAGE` clause as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. See [Section 13.1.17, “CREATE TABLE Syntax”](#), for more information.

Once table `ts_1` has been created as shown, you can perform `INSERT`, `SELECT`, `UPDATE`, and `DELETE` statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL Cluster NDB 7.2, only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see [Section 17.5.12.2, “Using Symbolic Links with Disk Data Objects”](#), for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```

mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1

```

```

-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
-> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
-> ENGINE NDBCLUSTER;

```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra “NULL row” provides additional information about undo log files. For more information and examples, see [Section 20.29.1](#), “The `INFORMATION_SCHEMA FILES` Table”.

It is also possible to view information about allocated and free disk space for each Disk Data table or table partition using the `ndb_desc` utility. For more information, see [Section 17.4.9](#), “`ndb_desc` — Describe NDB Tables”.

17.5.12.2. Using Symbolic Links with Disk Data Objects

The performance of a MySQL Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. In early versions of MySQL Cluster, there was no direct support for this in MySQL Cluster, but it was possible to achieve this separation using symbolic links as described in this section. MySQL Cluster NDB 7.2 supports the data node configuration parameters `FileSystemPathDD` [2084], `FileSystemPathDataFiles` [2084], and `FileSystemPathUndoFiles` [2085], which make the use of symbolic links for this purpose unnecessary. For more information about these parameters, see [Disk Data file system parameters](#).

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` [2042] as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

Note

In this example, we assume that the cluster's data node hosts are all using Linux operating systems. For other platforms, you may need to substitute your operating system's commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

```

shell> cd /data0/ndb_2_fs
shell> ls
D1 D10 D11 D2 D8 D9 LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata

```

You should now have two symbolic links:

```
shell> ls -l --hide=D*
lrwxrwxrwx 1 user group 30 2007-03-19 13:58 dndata -> /data1
lrwxrwxrwx 1 user group 30 2007-03-19 13:59 dnlogs -> /data2
```

We show this only for the data node with node ID 2; however, you must do this for *each* data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'dnlogs/undo1.log'
-> INITIAL_SIZE 150M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'dndata/data1.log'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 1G
-> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 157286400 2007-03-19 14:02 undo1.dat

shell> cd /data2
shell> ls -l
total 2099304
-rw-rw-r-- 1 user group 1073741824 2007-03-19 14:02 data1.dat
```

- If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using `/data0` for both data node file systems, but you wish to have the Disk Data files for both nodes on `/data1`. In this case, you can do something similar to what is shown here:

```
shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ln -s /data1/dn3 ndb_3_fs/dd
shell> ls -l --hide=D* ndb_2_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn3
```

- Now you can create a logfile group and tablespace using the symbolic link, like this:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'dd/undo1.log'
-> INITIAL_SIZE 150M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE=NDBCLUSTER;

mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'dd/data1.log'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 1G
-> ENGINE=NDBCLUSTER;
```

Verify that the files were created and placed correctly as shown here:

```
shell> cd /data1
shell> ls
```

```

dn2          dn3
shell> ls dn2
undo1.log   data1.log
shell> ls dn3
undo1.log   data1.log

```

17.5.12.3. MySQL Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 11.6, “Data Type Storage Requirements”](#).

You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see [Section 20.29.1, “The INFORMATION_SCHEMA FILES Table”](#).

Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a `TEXT` or `BLOB` column are stored in memory; only the remainder is stored on disk.
- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of `DataMemory` [2043] used per row from 4 to 8 bytes.

Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` [2083] is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

17.5.13. Adding MySQL Cluster Data Nodes Online

This section describes how to add MySQL Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

Important

Currently, you must add new data nodes to a MySQL Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

17.5.13.1. Adding MySQL Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding MySQL Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize `NDBCLUSTER` table data and indexes so that they are distributed across all data nodes, including the new ones. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed) or `BLOB` table data.

The redistribution for `NDBCLUSTER` tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using MySQL Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as hown in the following table:

| Failure occurs during: | Failure occurs in: | | |
|------------------------|---|---|--|
| | “Old” data nodes | “New” data nodes | System |
| Node group creation | <ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back | <ul style="list-style-type: none"> • If a node other than the master fails: The creation of the node group is always rolled forward. • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The creation of the node group is rolled forward. • If the internal commit point has not yet been reached. The creation of the node group is rolled back | <ul style="list-style-type: none"> • If the execution of <code>CREATE NODEGROUP</code> has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without. • If the execution of <code>CREATE NODEGROUP</code> has not yet reached the internal commit point: When restarted, the cluster does not include the new node group. |
| Table reorganization | <ul style="list-style-type: none"> • If a node other than the master fails: The table | <ul style="list-style-type: none"> • If a node other than the master fails: The table | <ul style="list-style-type: none"> • If the execution of an <code>ALTER ONLINE TABLE table REORGANIZE</code> |

| Failure occurs during: | Failure occurs in: | | |
|------------------------|---|---|---|
| | “Old” data nodes | “New” data nodes | System |
| | reorganization is always rolled forward. <ul style="list-style-type: none"> • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The table reorganization is rolled back. | reorganization is always rolled forward. <ul style="list-style-type: none"> • If the master fails: <ul style="list-style-type: none"> • If the internal commit point has been reached: The table reorganization is rolled forward. • If the internal commit point has not yet been reached. The table reorganization is rolled back. | PARTITION statement has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using the “new” data nodes. <ul style="list-style-type: none"> • If the execution of an ALTER ONLINE TABLE table REORGANIZE PARTITION statement has not yet reached the internal commit point: When the cluster is restarted, the data and indexes belonging to <i>table</i> are distributed using only the “old” data nodes. |

Dropping node groups. The `ndb_mgm` client supports a `DROP NODEGROUP` command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing `CREATE NODEGROUP` in the `ndb_mgm` client, but before issuing any `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements in the `mysql` client.
2. After dropping all `NDBCLUSTER` tables using `DROP TABLE`.

`TRUNCATE TABLE` does not work for this purpose because the data nodes continue to store the table definitions.

17.5.13.2. Adding MySQL Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to a MySQL Cluster. This procedure applies whether you are using `ndbd` or `ndbmta` binaries for the data node processes. For a more detailed example, see [Section 17.5.13.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”](#).

Assuming that you already have a running MySQL Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically

allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all MySQL Cluster management servers.

Important

All management servers must be restarted with the `--reload [2191]` or `--initial [2190]` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing MySQL Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial [2178]` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the MySQL Cluster.
5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the MySQL Cluster management client to create the new node group or node groups to which the new data nodes will belong.
7. Redistribute the cluster's data among all data nodes (including the new ones) by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

Note

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized using `ALTER ONLINE TABLE tbl REORGANIZE PARTITION`.

8. Reclaim the space freed on the “old” nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.

17.5.13.3. Adding MySQL Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new MySQL Cluster data nodes online, starting with a MySQL Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbnd default]
```

```
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This makes it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.5.29-ndb-7.2.10, Nodegroup: 0, Master)
id=2 @192.168.0.2 (5.5.29-ndb-7.2.10, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.5.29-ndb-7.2.10)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.5.29-ndb-7.2.10)
id=21 @192.168.0.21 (5.5.29-ndb-7.2.10)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:

```
USE n;

CREATE TABLE ips (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  country_code CHAR(2) NOT NULL,
  type CHAR(4) NOT NULL,
  ip_address varchar(15) NOT NULL,
  addresses BIGINT UNSIGNED DEFAULT NULL,
  date BIGINT UNSIGNED DEFAULT NULL
) ENGINE NDBCLUSTER;
```

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

**Note**

In this example, we show the single-threaded `ndbd` being used for the data node processes. However—beginning with MySQL Cluster NDB 7.0.4—you can also apply this example, if you are using the multi-threaded `ndbmt_d` by substituting `ndbmt_d` for `ndbd` wherever it appears in the steps that follow. (Bug #43108)

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add `[ndbd]` sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the `config.ini` file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2
[ndbd]
Id = 3
HostName = 192.168.0.3

[ndbd]
Id = 4
HostName = 192.168.0.4

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server. Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown

shell>
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload [2191]` or `--initial [2190]` option

so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO      -- NDB Cluster Management Server. 5.5.29-ndb-7.2.10
2008-12-08 17:29:23 [MgmSrvr] INFO      -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1      @192.168.0.1  (5.5.29-ndb-7.2.10, Nodegroup: 0, Master)
id=2      @192.168.0.2  (5.5.29-ndb-7.2.10, Nodegroup: 0)
id=3 (not connected, accepting connect from 192.168.0.3)
id=4 (not connected, accepting connect from 192.168.0.4)

[ndb_mgmd(MGM)] 1 node(s)
id=10     @192.168.0.10  (5.5.29-ndb-7.2.10)

[mysqld(API)]   2 node(s)
id=20     @192.168.0.20  (5.5.29-ndb-7.2.10)
id=21     @192.168.0.21  (5.5.29-ndb-7.2.10)
```

Step 3: Perform a rolling restart of the existing data nodes. This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.2.10)
Node 1: Started (version 7.1.26)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted

ndb_mgm> Node 2: Start initiated (version 7.2.10)

ndb_mgm> Node 2: Started (version 7.2.10)
```

Important

After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL `root` password for a given MySQL server instance:

```
shell> mysqladmin -uroot -ppassword shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
```

```

/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
    
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` [2178] option:

```
shell> ndbd -c 192.168.0.10 --initial
```

Note

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```

ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1   @192.168.0.1  (5.5.29-ndb-7.2.10, Nodegroup: 0, Master)
id=2   @192.168.0.2  (5.5.29-ndb-7.2.10, Nodegroup: 0)
id=3   @192.168.0.3  (5.5.29-ndb-7.2.10, no nodegroup)
id=4   @192.168.0.4  (5.5.29-ndb-7.2.10, no nodegroup)

[ndb_mgmd(MGM)] 1 node(s)
id=10  @192.168.0.10   (5.5.29-ndb-7.2.10)

[mysqld(API)]   2 node(s)
id=20  @192.168.0.20   (5.5.29-ndb-7.2.10)
id=21  @192.168.0.21   (5.5.29-ndb-7.2.10)
    
```

Step 6: Create a new node group. You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```

ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
    
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```

ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=1   @192.168.0.1  (5.5.29-ndb-7.2.10, Nodegroup: 0, Master)
id=2   @192.168.0.2  (5.5.29-ndb-7.2.10, Nodegroup: 0)
id=3   @192.168.0.3  (5.5.29-ndb-7.2.10, Nodegroup: 1)
id=4   @192.168.0.4  (5.5.29-ndb-7.2.10, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10  @192.168.0.10   (5.5.29-ndb-7.2.10)
    
```

```
[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.5.29-ndb-7.2.10)
id=21 @192.168.0.21 (5.5.29-ndb-7.2.10)
```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY

addresses Bigunsigned NULL AT=FIXED ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY

-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex

-- Per partition info --
Partition   Row count   Commit count   Frag fixed memory   Frag varsized memory
0             26086         26086             1572864               557056
1             26329         26329             1605632               557056

NDBT_ProgramExit: 0 - OK
```

You can cause the data to be redistributed among all of the data nodes by performing, for each `NDBCLUSTER` table, an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client. After issuing the statement `ALTER ONLINE TABLE ips REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```

shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
Version: 16777217

2          13105      13105         819200             294912
3          13093      13093         819200             294912

NDBT_ProgramExit: 0 - OK

```

Note

Normally, `ALTER [ONLINE] TABLE table_name REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new MySQL Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#).

In addition, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```

SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';

```

Note

The `INFORMATION_SCHEMA.TABLES.ENGINE` value for a MySQL Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to

create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

Note

Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created *after* the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed *prior* to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3
Nodegroup = 65536

[ndbd]
Id = 4
HostName = 192.168.0.4
Nodegroup = 65536

[mgm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
```

```

HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21

```

**Note**

In MySQL Cluster NDB 7.2, it is no longer necessary to perform the initial start of the cluster using `--nowait-nodes` [2180] option with `ndbd` or `ndbmt` as it was in some earlier versions of MySQL Cluster.

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with `NodeGroup = 65536` [2040], in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 192.168.0.10 --initial
```

The data nodes configured with `NodeGroup = 65536` [2040] are treated by the management server as though you had started nodes 1 and 2 using `--nowait-nodes=3,4` [2180] after waiting for a period of time determined by the setting for the `StartNoNodeGroupTimeout` [2062] data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

**Note**

`StartNoNodegroupTimeout` [2062] must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 192.168.0.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing MySQL Cluster tables cannot use the new nodes for data distribution until this has been done.)

17.5.14. Distributed MySQL Privileges for MySQL Cluster

MySQL Cluster NDB 7.2 introduces support for distributing MySQL users and privileges across all SQL nodes in a MySQL Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. In MySQL Cluster NDB 7.2 and later, an SQL file `ndb_dist_priv.sql` is provided with the MySQL Cluster distribution. This file can be found in the `share` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the *target* SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where `options` stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL `root` user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
-> FROM INFORMATION_SCHEMA.ROUTINES
-> WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
-> ORDER BY ROUTINE_TYPE;
```

| ROUTINE_NAME | ROUTINE_SCHEMA | ROUTINE_TYPE |
|---|----------------|--------------|
| mysql_cluster_privileges_are_distributed | mysql | FUNCTION |
| mysql_cluster_backup_privileges | mysql | PROCEDURE |
| mysql_cluster_move_grant_tables | mysql | PROCEDURE |
| mysql_cluster_move_privileges | mysql | PROCEDURE |
| mysql_cluster_restore_local_privileges | mysql | PROCEDURE |
| mysql_cluster_restore_privileges | mysql | PROCEDURE |
| mysql_cluster_restore_privileges_from_local | mysql | PROCEDURE |

```
7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to `NDB`. Two sets of copies are created in the `mysql` database:

- A set of local copies that use the `MyISAM` storage engine, and named by adding the suffix `_backup` to the original privilege table names.
- A set of distributed copies (using `NDBCLUSTER`). These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
mysql host user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT(
-> 'Conversion ',
-> IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
-> '.')
-> AS Result;
```

| Result |
|-----------------------|
| Conversion succeeded. |

```
1 row in set (0.00 sec)
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns 1 if all of the privilege tables are distributed; otherwise, it returns 0.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
->     WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
->     ORDER BY ENGINE;
```

| TABLE_NAME | ENGINE |
|-------------------------|------------|
| host_backup | MyISAM |
| db_backup | MyISAM |
| columns_priv_backup | MyISAM |
| user_backup | MyISAM |
| tables_priv_backup | MyISAM |
| proxies_priv_backup | MyISAM |
| procs_priv_backup | MyISAM |
| ndb_user_backup | ndbcluster |
| ndb_tables_priv_backup | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup | ndbcluster |
| ndb_host_backup | ndbcluster |
| ndb_db_backup | ndbcluster |
| ndb_columns_priv_backup | ndbcluster |

```
14 rows in set (0.00 sec)
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

Note

Formerly, after `mysql_cluster_move_privileges` was executed, you sometimes needed to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges. In MySQL Cluster NDB 7.2.4 and later, this is no longer necessary, as SQL nodes automatically execute a `FLUSH PRIVILEGES` statement when joining a MySQL Cluster where distributed privileges are in use.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes privileges associated with views and stored routines. While automatic distribution of views and stored routines is not currently supported, you can attempt to distribute stored routines by issuing a statement such as `ALTER TABLE mysql.proc ENGINE = NDB`, but you must verify manually that any tables referenced by the stored routines exist on all SQL nodes, since MySQL Cluster has no support at the present time for doing this automatically. There is currently no way to distribute views among MySQL Cluster SQL nodes, other than by creating them manually on each SQL node. If you do this, you must make certain that all base tables referenced by the views use the `NDB` storage engine; otherwise, the views are likely to diverge very quickly.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial` [2178]), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` [461] when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` [461] option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` [2222] from a backup made using `START BACKUP` in the `ndb_mgm` client. (The MyISAM tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` [2222] option causes it to do so.

Important

Applications that access MySQL Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other NDB tables. In particular, you should keep in mind that *NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions.*

17.5.15. NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting Ndb objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by NDBCLUSTER. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
```

| Variable_name | Value |
|--|-------|
| Ndb_api_wait_exec_complete_count_session | 0 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 0 |
| Ndb_api_wait_nanos_count_session | 0 |

+-----+-----+
60 rows in set (0.00 sec)

Each `Ndb` object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one `Ndb` object concurrently, it is also possible to obtain a summed view of counters from all `Ndb` objects belonging to a given `Ndb_cluster_connection`.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. *This is in spite of the fact that their values can be obtained as either session or global status variables in the `mysql` client.* This means that specifying the `SESSION` or `GLOBAL` keyword with `SHOW STATUS` has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the `SESSION_STATUS` or the `GLOBAL_STATUS` table.

- *Session counters (session specific)*

Session counters relate to the `Ndb` objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as “`_session` variables”, with a leading underscore.

- *Slave counters (global)*

This set of counters relates to the `Ndb` objects used by the replication slave SQL thread, if any. If this `mysqld` does not act as a replication slave, or does not use `NDB` tables, then all of these counts are 0.

We refer to the related status variables as “`_slave` variables” (with a leading underscore).

- *Injector counters (global)*

Injector counters relate to the `Ndb` object used to listen to cluster events by the binlog injector thread. Even when not writing a binary log, `mysqld` processes attached to a MySQL Cluster continue to listen for some events, such as schema changes.

We refer to the status variables that correspond to NDB API injector counters as “`_injector` variables” (with a leading underscore).

- *Server (Global) counters (global)*

This set of counters relates to all `Ndb` objects currently used by this `mysqld`. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the `NDB` utility thread.

We refer to the status variables that correspond to these counters as “global variables” or “`mysqld`-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `_session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 1 |
| Ndb_api_wait_nanos_count_session | 8144375 |
| Ndb_api_bytes_sent_count_session | 68 |
| Ndb_api_bytes_received_count_session | 84 |
| Ndb_api_trans_start_count_session | 1 |

```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
-> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
```

| VARIABLE_NAME | VARIABLE_VALUE |
|------------------------------------|----------------|
| NDB_API_WAIT_EXEC_COMPLETE_COUNT | 4 |
| NDB_API_WAIT_SCAN_RESULT_COUNT | 3 |
| NDB_API_WAIT_META_REQUEST_COUNT | 28 |
| NDB_API_WAIT_NANOS_COUNT | 53756398 |
| NDB_API_BYTES_SENT_COUNT | 1060 |
| NDB_API_BYTES_RECEIVED_COUNT | 9724 |
| NDB_API_TRANS_START_COUNT | 3 |
| NDB_API_TRANS_COMMIT_COUNT | 2 |
| NDB_API_TRANS_ABORT_COUNT | 0 |
| NDB_API_TRANS_CLOSE_COUNT | 3 |
| NDB_API_PK_OP_COUNT | 2 |
| NDB_API_UK_OP_COUNT | 0 |
| NDB_API_TABLE_SCAN_COUNT | 1 |
| NDB_API_RANGE_SCAN_COUNT | 0 |
| NDB_API_PRUNED_SCAN_COUNT | 0 |
| NDB_API_SCAN_BATCH_COUNT | 0 |
| NDB_API_READ_ROW_COUNT | 2 |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2 |
| NDB_API_EVENT_DATA_COUNT | 0 |
| NDB_API_EVENT_NONDATA_COUNT | 0 |
| NDB_API_EVENT_BYTES_COUNT | 0 |

21 rows in set (0.09 sec)

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
```

| Variable_name | Value |
|--------------------------------------|-------|
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nondata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |
| Ndb_api_event_data_count | 0 |
| Ndb_api_event_nondata_count | 0 |
| Ndb_api_event_bytes_count | 0 |

6 rows in set (0.00 sec)

`_injector` status variables are not implemented for any other NDB API counters, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
```

| Variable_name | Value |
|--------------------------------------|-------|
| Ndb_api_event_data_count_injector | 0 |
| Ndb_api_event_nondata_count_injector | 0 |
| Ndb_api_event_bytes_count_injector | 0 |

3 rows in set (0.00 sec)

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

| Counter Name | <p>Description</p> <p>Status Variables (by statistic type):</p> <ul style="list-style-type: none"> • Session • Slave • Injector • Server |
|-----------------------|---|
| WaitExecCompleteCount | <p>Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients.</p> <ul style="list-style-type: none"> • Ndb_api_wait_exec_complete_count_session [2161] • Ndb_api_wait_exec_complete_count_slave [2161] • [none] • Ndb_api_wait_exec_complete_count [2162] |
| WaitScanResultCount | <p>Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.</p> <ul style="list-style-type: none"> • Ndb_api_wait_scan_result_count_session [2162] • Ndb_api_wait_scan_result_count_slave [2162] • [none] • Ndb_api_wait_scan_result_count [2162] |
| WaitMetaRequestCount | <p>Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).</p> <ul style="list-style-type: none"> • Ndb_api_wait_meta_request_count_session [2162] • Ndb_api_wait_meta_request_count_slave [2162] • [none] • Ndb_api_wait_meta_request_count [2163] |
| WaitNanosCount | <p>Total time (in nanoseconds) spent waiting for some type of signal from the data nodes.</p> <ul style="list-style-type: none"> • Ndb_api_wait_nanos_count_session [2163] • Ndb_api_wait_nanos_count_slave [2163] • [none] • Ndb_api_wait_nanos_count [2163] |
| BytesSentCount | <p>Amount of data (in bytes) sent to the data nodes</p> <ul style="list-style-type: none"> • Ndb_api_bytes_sent_count_session [2163] |

| Counter Name | Description Status Variables (by statistic type): <ul style="list-style-type: none"> • Session • Slave • Injector • Server |
|------------------|---|
| | <ul style="list-style-type: none"> • Ndb_api_bytes_sent_count_slave [2164] • [none] • Ndb_api_bytes_sent_count [2164] |

| Counter Name | Description |
|-----------------------------------|--|
| | <p>Status Variables (by statistic type):</p> <ul style="list-style-type: none"> • Session • Slave • Injector • Server |
| | <ul style="list-style-type: none"> • [none] • Ndb_api_event_nondata_count_injector [2171] • Ndb_api_event_nondata_count [2171] |
| <code>EventBytesRecvdCount</code> | <p>Number of bytes of events received.</p> <ul style="list-style-type: none"> • [none] • [none] • Ndb_api_event_bytes_count_injector [2171] • Ndb_api_event_bytes_count [2171] |

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_commit_count_slave | 0 |
| Ndb_api_trans_commit_count | 2 |
+-----+-----+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an NDB table, named `t`, that has a single column:

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 2 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 3 |
| Ndb_api_wait_nanos_count_session | 820705 |
| Ndb_api_bytes_sent_count_session | 132 |
| Ndb_api_bytes_received_count_session | 372 |
| Ndb_api_trans_start_count_session | 1 |
| Ndb_api_trans_commit_count_session | 1 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 1 |
+-----+-----+
```

```

| Ndb_api_pk_op_count_session | 1 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 1 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)

```

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 8 |
| Ndb_api_wait_scan_result_count_session | 0 |
| Ndb_api_wait_meta_request_count_session | 17 |
| Ndb_api_wait_nanos_count_session | 706871709 |
| Ndb_api_bytes_sent_count_session | 2376 |
| Ndb_api_bytes_received_count_session | 3844 |
| Ndb_api_trans_start_count_session | 4 |
| Ndb_api_trans_commit_count_session | 4 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 4 |
| Ndb_api_pk_op_count_session | 6 |
| Ndb_api_uk_op_count_session | 0 |
| Ndb_api_table_scan_count_session | 0 |
| Ndb_api_range_scan_count_session | 0 |
| Ndb_api_pruned_scan_count_session | 0 |
| Ndb_api_scan_batch_count_session | 0 |
| Ndb_api_read_row_count_session | 2 |
| Ndb_api_trans_local_read_row_count_session | 1 |
+-----+-----+
18 rows in set (0.00 sec)

```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`: Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```

mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)

mysql> SHOW STATUS LIKE 'ndb_api%session%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_api_wait_exec_complete_count_session | 11 |
| Ndb_api_wait_scan_result_count_session | 6 |
| Ndb_api_wait_meta_request_count_session | 20 |
| Ndb_api_wait_nanos_count_session | 707370418 |
| Ndb_api_bytes_sent_count_session | 2724 |
| Ndb_api_bytes_received_count_session | 4116 |
| Ndb_api_trans_start_count_session | 7 |
| Ndb_api_trans_commit_count_session | 6 |
| Ndb_api_trans_abort_count_session | 0 |
| Ndb_api_trans_close_count_session | 7 |
| Ndb_api_pk_op_count_session | 8 |
| Ndb_api_uk_op_count_session | 0 |

```

```

/ Ndb_api_table_scan_count_session          / 1          /
| Ndb_api_range_scan_count_session         | 0          |
| Ndb_api_pruned_scan_count_session        | 0          |
| Ndb_api_scan_batch_count_session         | 0          |
/ Ndb_api_read_row_count_session           / 3          /
/ Ndb_api_trans_local_read_row_count_session / 2          /
+-----+-----+
18 rows in set (0.00 sec)

```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session` [2166], or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.
- By comparing successive values for `Ndb_api_wait_nanos_count_session` [2163], we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

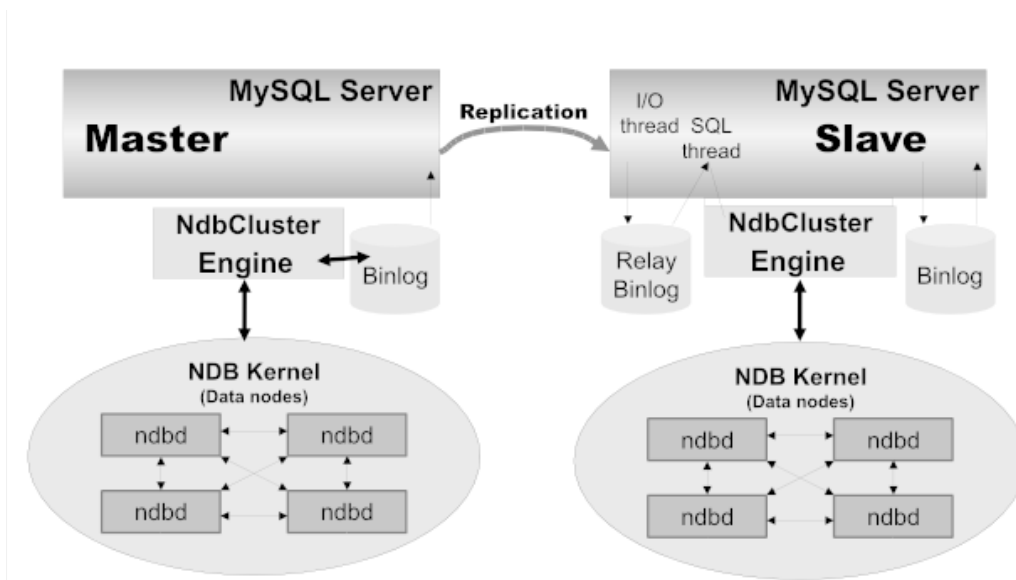

On platforms with without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session` [2163], `Ndb_api_wait_nanos_count_slave` [2163], or `Ndb_api_wait_nanos_count` [2163].

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` [2169] and `Ndb_api_trans_local_read_row_count_session` [2170].

17.6. MySQL Cluster Replication

MySQL Cluster supports *asynchronous replication*, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 16, Replication](#)).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the slave's copies of the replicated tables (see [Replication from NDB to non-NDB tables](#)). However, for maximum availability, it is possible (and preferable) to replicate from one MySQL Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log (*binlog*). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

For information about performing point-in-time recovery with MySQL Cluster and MySQL Cluster Replication, see [Section 17.6.9.2, “Point-In-Time Recovery Using MySQL Cluster Replication”](#).

NDB API *_slave* status variables. NDB API counters can provide enhanced monitoring capabilities on MySQL Cluster replication slaves. These are implemented as NDB statistics *_slave* status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a slave in MySQL Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting MySQL Cluster Replication. [Section 17.5.15, “NDB API Statistics Counters and Variables”](#), provides additional information.

Replication from NDB to non-NDB tables. It is possible to replicate NDB tables from a MySQL Cluster acting as the master to tables using other MySQL storage engines such as `InnoDB` or `MyISAM` on a slave `mysqld`. However, because of differences between the version of `mysqld` provided with MySQL Cluster and that included with MySQL Server 5.5, the slave server must also use a `mysqld` binary from the MySQL Cluster distribution. See [Section 17.6.2, “General Requirements for MySQL Cluster Replication”](#).

17.6.1. MySQL Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

| Symbol or Abbreviation | Description (Refers to...) |
|------------------------|---|
| <i>M</i> | The cluster serving as the (primary) replication master |

| Symbol or Abbreviation | Description (Refers to...) |
|--------------------------|--|
| <i>S</i> | The cluster acting as the (primary) replication slave |
| <code>shellM></code> | Shell command to be issued on the master cluster |
| <code>mysqlM></code> | MySQL client command issued on a single MySQL server running as an SQL node on the master cluster |
| <code>mysqlM*></code> | MySQL client command to be issued on all SQL nodes participating in the replication master cluster |
| <code>shellS></code> | Shell command to be issued on the slave cluster |
| <code>mysqlS></code> | MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster |
| <code>mysqlS*></code> | MySQL client command to be issued on all SQL nodes participating in the replication slave cluster |
| <i>C</i> | Primary replication channel |
| <i>C'</i> | Secondary replication channel |
| <i>M'</i> | Secondary replication master |
| <i>S'</i> | Secondary replication slave |

17.6.2. General Requirements for MySQL Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=ROW` [436], as described in [Section 17.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 16.1.2, “Replication Formats”](#).

Important

If you attempt to use MySQL Cluster Replication with `--binlog-format=STATEMENT` [436], replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see [Section 17.6.4, “MySQL Cluster Replication Schema and Tables”](#)). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

In MySQL Cluster NDB 7.2.1 and later, the default value for the `--binlog-format` [436] option is `STATEMENT` (for MySQL Cluster releases based on MySQL Server 5.1, the default was `MIXED`). You must change the binary logging format to `ROW` manually on all MySQL Servers on the master MySQL Cluster, prior to starting MySQL Cluster replication. As just described previously, you can do this on startup using the `--binlog-format` [436] option. You can also change the binary logging format at runtime by setting the global `binlog_format` [1899] system variable. The latter method represents a change from MySQL Cluster NDB 7.1 and earlier versions of MySQL Cluster, where MySQL Servers used as MySQL Cluster SQL nodes switched their logging format automatically when the cluster acted as a replication master.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see [Section 16.4.2, “Replication Compatibility Between MySQL Versions”](#)). It is due to such differences between the binaries in the MySQL Cluster and MySQL Server 5.5 distributions that MySQL Cluster Replication has the additional requirement that both `mysqld` binaries come from a MySQL Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same MySQL Cluster distribution for all master and slave `mysqld` binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

Note

It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see [Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more specific information concerning the differences between the two replication formats.

17.6.3. Known Issues in MySQL Cluster Replication

This section discusses known problems or issues when using replication with MySQL Cluster NDB 7.2.

Loss of master-slave connection. A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` [2066] and `TimeBetweenEpochs` [2065] configuration parameters). If this occurs, *it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master's binary log*. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. MySQL Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are

server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#), for more information about what to do in such circumstances.

Important

Because MySQL Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see [Section 17.6.7, “Using Two Replication Channels for MySQL Cluster Replication”](#), and [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#).

However, if you are replicating from a standalone MySQL server to a MySQL Cluster, one channel is usually sufficient.

Circular replication. MySQL Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1, thus completing the circle. Each MySQL Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates [1870]` option

This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates` [1870]. This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

Note

The **NDB** storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of MySQL Cluster. This is equivalent to setting the global `slave_exec_mode` [1887] system variable to `IDEMPOTENT`. This is also required for multi-master replication when using MySQL Cluster. (Bug #31609)

It is not necessary to set `slave_exec_mode` [1887] in MySQL Cluster replication; MySQL Cluster does this automatically for all **NDB** tables and ignores any attempts to set this variable explicitly.

MySQL Cluster replication and primary keys. In the event of a node failure, errors in replication of **NDB** tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all **NDB** tables being replicated have primary keys.

MySQL Cluster Replication and Unique Keys. In older versions of MySQL Cluster, operations that updated values of unique key columns of **NDB** tables could result in duplicate-key errors when replicated.

This issue is solved for replication between [NDB](#) tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by [NDB](#). Thus, updates of unique keys when replicating from [NDB](#) to a different storage engine such as [MyISAM](#) or [InnoDB](#) are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using [NDB](#) table such as `t`, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```
CREATE TABLE t (
  p INT PRIMARY KEY,
  c INT,
  UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following `UPDATE` statement on `t` succeeded on the master, since the rows affected are processed in the order determined by the `ORDER BY` option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

Note

Every [NDB](#) table is implicitly partitioned by key when it is created. See [Section 18.2.5, “KEY Partitioning”](#), for more information.

Restarting with `--initial`. Restarting the cluster with the `--initial` [2178] option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

Replication from [NDB](#) to other storage engines. It is possible to replicate an [NDB](#) table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the [NDB](#) storage engine for this to work).
- Using a storage engine does not perform binary logging for slave tables requires special handling.
- Use of a non-transactional storage engine for slave tables also requires special handling.

The next few paragraphs provide additional information about each of the issues just described.

Multiple masters not supported when replicating [NDB](#) to other storage engines. For replication from [NDB](#) to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between MySQL Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between [NDB](#) and a different storage engine. (However, a MySQL Cluster database *can* simultaneously replicate to multiple slave MySQL Cluster databases.) If the master uses [NDB](#) tables, it is still possible to have more

than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

Replicating NDB to a slave storage engine that does not perform binary logging. If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0` [555].
- **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
- **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status` [1878]. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` [1880] option instead.

Important

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one MySQL Cluster to another. See [Replication and binary log filtering rules with replication between MySQL Clusters](#), for details.

Replication from NDB to a nontransactional storage engine. When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0` [2373], which forces updates to be logged as writes (rather than as updates).

In addition, when replicating from NDB to a storage engine that does not implement transactions, if the slave fails to apply any row changes from a given transaction, it does not roll back the rest of the transaction. (This is true when replicating tables using any transactional storage engine—not only NDB—to a nontransactional storage engine.) Because of this, it cannot be guaranteed that transactional consistency will be maintained on the slave in such cases.

Replication and binary log filtering rules with replication between MySQL Clusters. If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db` [1894], or `--binlog-ignore-db` [1896] to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between MySQL Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` [1875] (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that *only* tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql` [1875], `--binlog-do-db=mysql` [1894], or `--replicate-do-table=mysql.ndb_apply_status` [1878] to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` [1894] (and no other `--binlog-do-db` [1894] options) means that changes *only* to tables in database `db_name` are written to the binary log. In this case, you should

also use `--replicate-do-db=mysql` [1875], `--binlog-do-db=mysql` [1894], or `--replicate-do-table=mysql.ndb_apply_status` [1878] to ensure that `mysql.ndb_apply_status` is populated on slaves.

- Using `--replicate-ignore-db=mysql` [1877] means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` [1878] to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` [1896] means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` [1878] to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

- Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).
- Its own `--binlog-do-db` [1894] or `--binlog-ignore-db` [1896] option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see [Section 5.2.4, “The Binary Log”](#).

If you are replicating a MySQL Cluster to a slave that uses a storage engine other than `NDB`, the considerations just given previously may not apply, as discussed elsewhere in this section.

MySQL Cluster Replication and IPv6. Currently, the `NDB` API and `MGM` API do not support IPv6. However, MySQL Servers—including those acting as SQL nodes in a MySQL Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between MySQL Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

However, all connections originating *within* the MySQL Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all MySQL Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

Attribute promotion and demotion. MySQL Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` [1889] global server system variable.

For more information about attribute promotion and demotion in MySQL Cluster, see [Row-based replication: attribute promotion and demotion](#).

17.6.4. MySQL Cluster Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the `MyISAM` storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

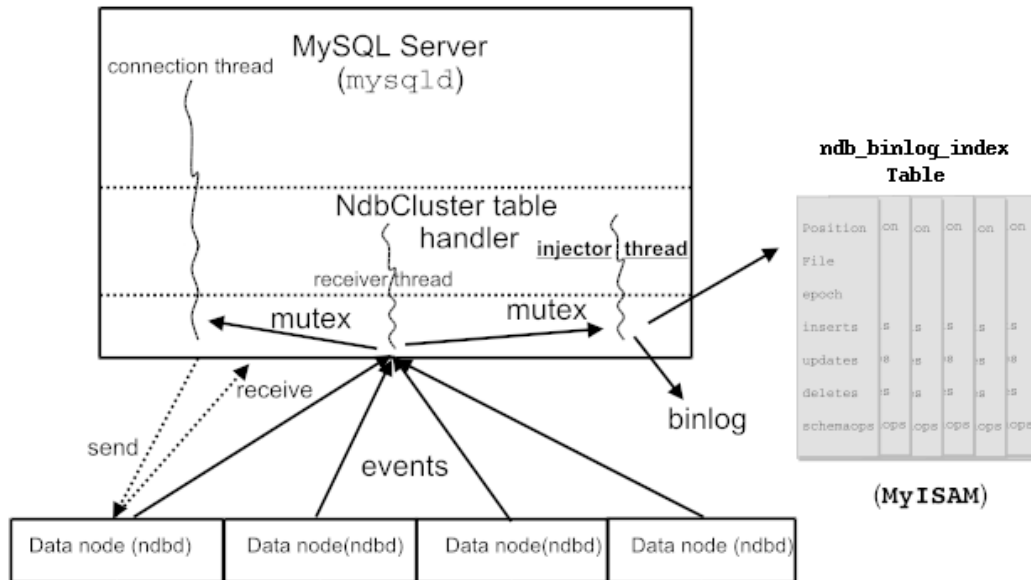

```
CREATE TABLE `ndb_binlog_index` (  
  `Position` BIGINT(20) UNSIGNED NOT NULL,  
  `File` VARCHAR(255) NOT NULL,  
  `epoch` BIGINT(20) UNSIGNED NOT NULL,  
  `inserts` INT(10) UNSIGNED NOT NULL,  
  `updates` INT(10) UNSIGNED NOT NULL,  
  `deletes` INT(10) UNSIGNED NOT NULL,  
  `schemaops` INT(10) UNSIGNED NOT NULL,  
  `orig_server_id` INT(10) UNSIGNED NOT NULL,  
  `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,  
  `gci` INT(10) UNSIGNED NOT NULL,  
  `next_position` bigint(20) unsigned NOT NULL,  
  `next_file` varchar(255) NOT NULL,  
  PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)  
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

The `next_position` and `next_file` columns were added in MySQL Cluster NDB 7.2.6; see [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#), for more information about using these columns.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.

MySQL Replication Between Clusters, Injecting into Binlog

An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the `NDBCLUSTER` storage engine, as shown here:

```
CREATE TABLE `ndb_apply_status` (
  `server_id` INT(10) UNSIGNED NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `log_name` VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
  `start_pos` BIGINT(20) UNSIGNED NOT NULL,
  `end_pos` BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

This table is populated only on slaves; on the master, no `DataMemory [2043]` is allocated to it. Since this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see [Replication and binary log filtering rules with replication between MySQL Clusters](#).

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the `NDB` binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the `NDB` storage engine. The `NDB binlog injector thread` receives events directly from the `NDB` storage engine. The `NDB` injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the `ndb_binlog_index` table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.ndb_binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See [Section 13.7.5.3, "SHOW BINLOG EVENTS Syntax"](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

The `ndb_schema` table is used to track schema changes made to `NDB` tables. It is defined as shown here:

```
CREATE TABLE ndb_schema (
  `db` VARBINARY(63) NOT NULL,
  `name` VARBINARY(63) NOT NULL,
  `slock` BINARY(32) NOT NULL,
  `query` BLOB NOT NULL,
  `node_id` INT UNSIGNED NOT NULL,
  `epoch` BIGINT UNSIGNED NOT NULL,
  `id` INT UNSIGNED NOT NULL,
  `version` INT UNSIGNED NOT NULL,
  `type` INT UNSIGNED NOT NULL,
  PRIMARY KEY USING HASH (db,name)
) ENGINE=NDB DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the `ndb_schema` table is not visible either to MySQL `SHOW` statements, or in any `INFORMATION_SCHEMA` tables; however, it can be seen in the output of `ndb_show_tables`, as shown here:

```
shell> ndb_show_tables -t 2
id   type           state   logging database  schema  name
4    UserTable      Online Yes      mysql     def     ndb_apply_status
5    UserTable      Online Yes      ndbworld def     City
6    UserTable      Online Yes      ndbworld def     Country
3    UserTable      Online Yes      mysql     def     NDB$BLOB_2_3
7    UserTable      Online Yes      ndbworld def     CountryLanguage
2    UserTable      Online Yes      mysql     def     ndb_schema

NDBT_ProgramExit: 0 - OK
```

It is also possible to `SELECT` from this table in `mysql` and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='City' \G
***** 1. row *****
      db: ndbworld
      name: City
      slock:
      query: alter table City engine=ndb
node_id: 4
  epoch: 0
    id: 0
version: 0
  type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.

Note

When performing schema changes on `NDB` tables, applications should wait until the `ALTER TABLE` statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the `ndb_apply_status` table or the `ndb_schema` table does not exist on the slave, `ndb_restore` re-creates the missing table or tables (Bug #14612).

Conflict resolution for MySQL Cluster Replication requires the presence of an additional `mysql.ndb_replication` table. Currently, this table must be created manually. For information about how to do this, see [Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”](#).

17.6.5. Preparing the MySQL Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 17.6.2, “General Requirements for MySQL Cluster Replication”](#)).
2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'slave_user'@'slave_host'
-> IDENTIFIED BY 'slave_password';
```

In the previous statement, `slave_user` is the slave account user name, `slave_host` is the host name or IP address of the replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name “myslave,” logging in from the host named “rep-slave,” and using the password “53cr37,” use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'myslave'@'rep-slave'
-> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='master_host',
-> MASTER_PORT=master_port,
-> MASTER_USER='slave_user',
-> MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is “rep-master,” using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='rep-master',
-> MASTER_PORT=3306,
-> MASTER_USER='myslave',
-> MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

To provide replication backup capability, you also need to add an `ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See [Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#), for details.

For additional options that can be set in `my.cnf` for replication slaves, see [Section 16.1.3, “Replication and Binary Logging Options and Variables”](#).

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in [Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See [Section 16.1.2, “Replication Formats”](#).) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See [Section 17.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#), for information regarding the latter option.

17.6.6. Starting MySQL Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
--log-bin --binlog-format=ROW &
```

In the previous statement, `id` is this server's unique ID (see [Section 17.6.2, “General Requirements for MySQL Cluster Replication”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the command just shown, *id* is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

- It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO
-> MASTER_LOG_FILE='',
-> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

- Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysqlS> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 17.6.7, “Using Two Replication Channels for MySQL Cluster Replication”](#).

It is also possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by setting the `slave_allow_batching` [2155] system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON |
| slave_compressed_protocol | OFF |
| slave_load_tmpdir | /tmp |
| slave_net_timeout | 3600 |
| slave_skip_errors | OFF |
| slave_transaction_retries | 10 |
+-----+-----+
6 rows in set (0.00 sec)
```

17.6.7. Using Two Replication Channels for MySQL Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

| Server ID | Description |
|-----------|---|
| 1 | Master - primary replication channel (M) |
| 2 | Master - secondary replication channel (M') |
| 3 | Slave - primary replication channel (S) |
| 4 | Slave - secondary replication channel (S') |

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
             --log-bin --binlog-format=ROW &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
           --log-bin --binlog-format=ROW &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
           --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
           --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

17.6.8. Implementing Failover with MySQL Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster.

Prior to MySQL Cluster NDB 7.2.6, you should use the following query to accomplish this task:

```
mysqlM'> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

Beginning with MySQL Cluster NDB 7.2.6, you can take advantage of the improved binary logging of DDL statements implemented in those and later versions by using the following query to obtain the needed records from the master's `ndb_binlog_index` table:

```
mysqlM'> SELECT
-> @file:=SUBSTRING_INDEX(next_file, '/', -1),
-> @pos:=next_position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch = @latest
-> ORDER BY epoch ASC LIMIT 1;
```

In either case, these are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

Important

If (and only if) you use the second of the two queries just shown against `ndb_binlog_index` (that is, the query that employs the `next_position` and `next_file` columns), you must ensure that the slave `mysqld` is started

with `--slave-skip-errors=ddl_exist_errors [1883]` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

- Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
->     MASTER_LOG_FILE='@file',
->     MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

Note

`@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

- You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqlS`:

```
mysqlS'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from *M* to *S'*, or from *M'* to *S*; however, this has not yet been tested.

17.6.9. MySQL Cluster Backups With MySQL Cluster Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 17.6.5, “Preparing the MySQL Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

- There are two different methods by which the backup may be started.
 - Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the master cluster, and `port` is the management server's port number:

```
ndb-connectstring=management_host[:port]
```

**Note**

The port number needs to be specified only if the default port (1186) is not being used. See [Section 17.2.3, “Initial Configuration of MySQL Cluster”](#), for more information about ports and port allocation in MySQL Cluster.

In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shellM> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see [Section 17.6.5, “Preparing the MySQL Cluster for Replication”](#)), this would be executed as follows:

```
shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It *is* necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

**Important**

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

It is important to make sure that the slave's `apply_status` table does not contain any records prior to running the restore process. You can accomplish this by running this SQL statement on the slave:

```
mysqlS> DELETE FROM mysql.ndb_apply_status;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \  
-b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in [Section 17.6, “MySQL Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
-r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See [Section 17.4.18, “ndb_restore — Restore a MySQL Cluster Backup”](#).)

- Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in [Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”](#)):

```
mysqlS> SELECT @latest:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

- Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

- Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

- Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 17.5.3, “Online Backup of MySQL Cluster”](#).

17.6.9.1. MySQL Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see [Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”](#)). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w

    $sth->finish;
    print "\tSlave has been updated. You may now start the slave.\n";
}

# end reset-slave.pl

```

17.6.9.2. Point-In-Time Recovery Using MySQL Cluster Replication

Point-in-time recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing

point-in-time recovery of MySQL Cluster tables with MySQL Cluster and MySQL Cluster Replication can be accomplished using a native `NDB` data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of MySQL Cluster, it is necessary to follow the steps shown here:

1. Back up all `NDB` databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see [Section 17.5.3, “Online Backup of MySQL Cluster”](#)).
2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)
4. Locate the last known good backup.
5. Clear the data node file systems (using `ndbd --initial [2178]` or `ndbmtdd --initial [2178]`).

Note

MySQL Cluster Disk Data tablespace and log files are not removed by `--initial [2178]`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.
7. Execute `ndb_restore`, restoring all data. You must include the `--restore_epoch [2222]` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See [Section 17.4.18, “ndb_restore — Restore a MySQL Cluster Backup”](#), for more information.)
8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.
9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

```
SELECT @LATEST_EPOCH:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

```
SELECT Position, @FIRST_FILE:=File
FROM mysql.ndb_binlog_index
WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).)

See also [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#), for more information about the binary log, replication, and incremental recovery.

17.6.10. MySQL Cluster Replication: Multi-Master and Circular Replication

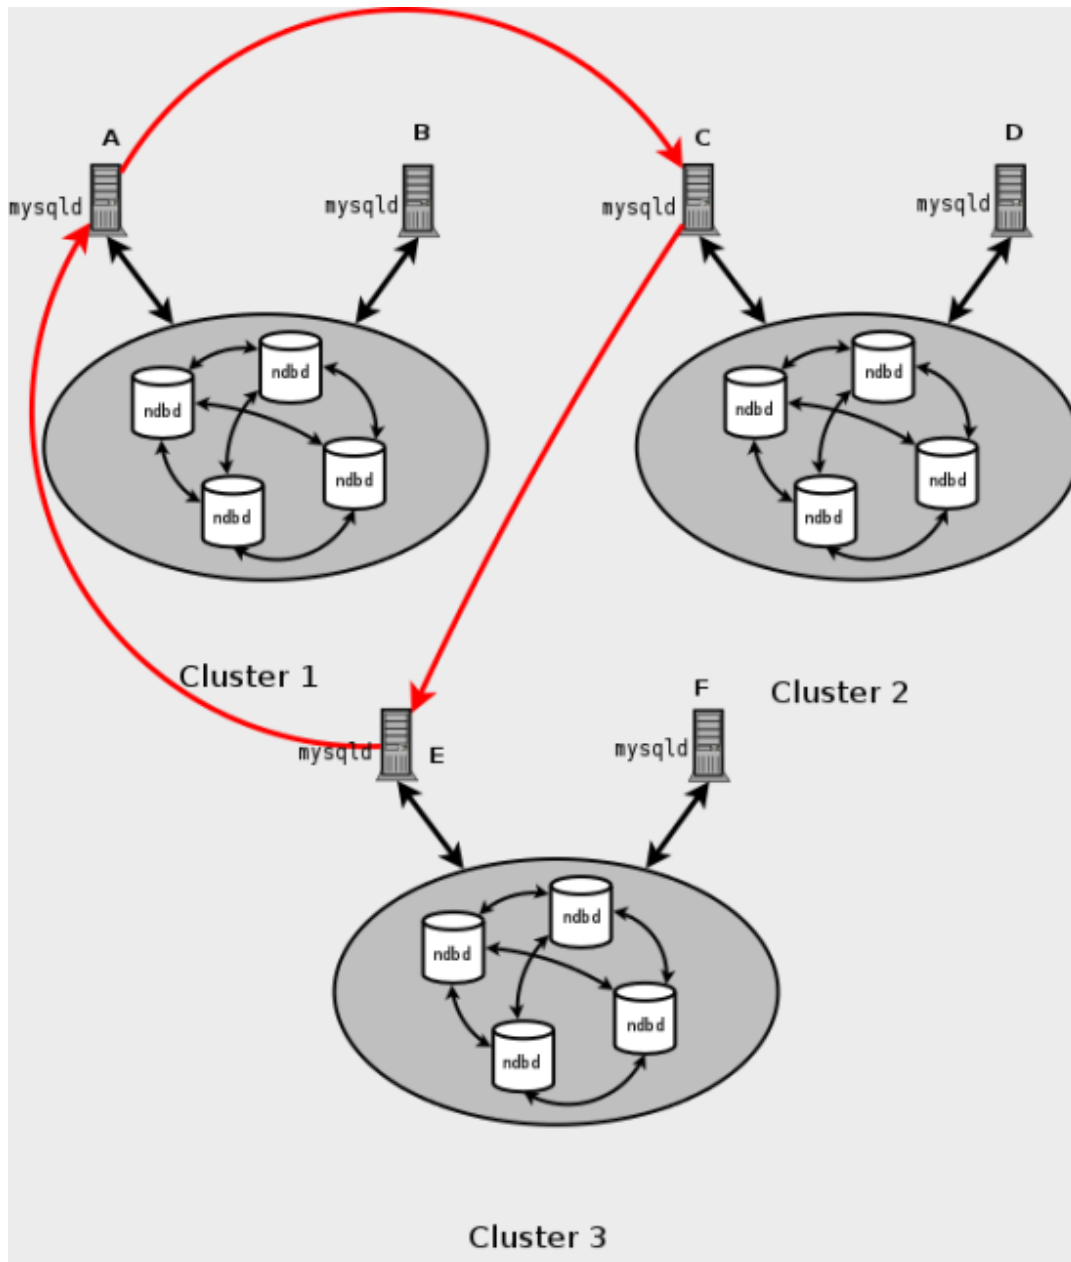

It is possible to use MySQL Cluster in multi-master replication, including circular replication between a number of MySQL Clusters.

Circular replication example. In the next few paragraphs we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates`. This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Important**

You should execute the following statement before starting circular replication:

```
mysql> SET GLOBAL SLAVE_EXEC_MODE = 'IDEMPOTENT';
```

This is necessary to suppress duplicate-key and other errors that otherwise break circular replication in MySQL Cluster. `IDEMPOTENT` mode is also required for multi-master replication when using MySQL Cluster. (Bug #31609)

See [slave_exec_mode \[1887\]](#), for more information.

Using NDB-native backup and restore to initialize a slave MySQL Cluster. When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one MySQL Cluster to create a backup and then applying this backup on another MySQL Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second MySQL Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`.

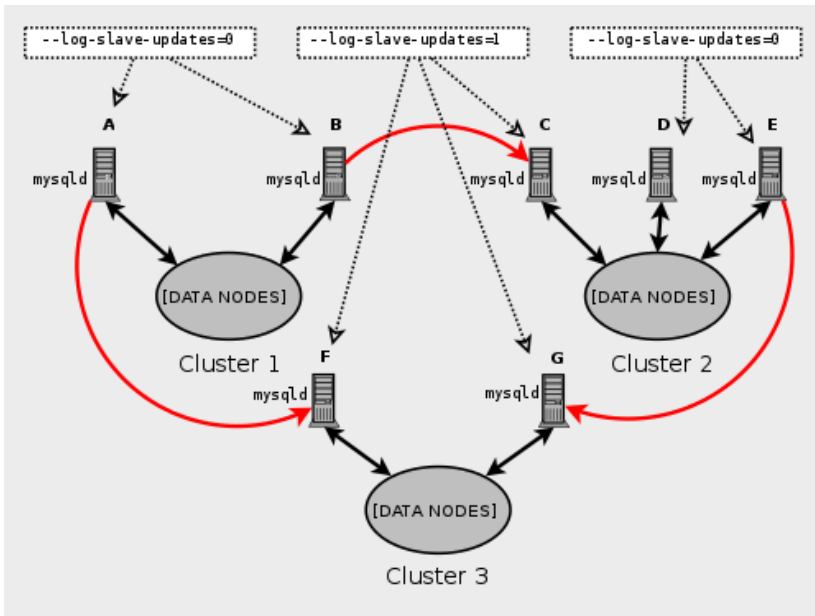

This is a known issue which we intend to address in a future release.

Multi-master failover example. In this section, we discuss failover in a multi-master MySQL Cluster replication setup with three MySQL Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given MySQL Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

MySQL servers acting as replication slaves must be run with the `--log-slave-updates` [1870] option. Which `mysqld` processes require this option is also shown in the preceding diagram.

Note

Using the `--log-slave-updates` [1870] option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between MySQL Clusters is asynchronous, there is no guarantee that Cluster 3's updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```
mysqlC> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status
-> WHERE server_id=1;

mysqlC> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE orig_epoch >= @latest
-> AND orig_server_id = 1
-> ORDER BY epoch ASC LIMIT 1;
```

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```
mysqlF> CHANGE MASTER TO
-> MASTER_HOST = 'serverC'
```

```
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#), and [Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”](#).

17.6.11. MySQL Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update to the row on a given master should be applied on the slave.

Some types of conflict resolution supported by MySQL Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a “timestamp” column (although its type cannot be `TIMESTAMP`, as explained later in this section); epoch-based conflict resolution functions introduced in MySQL Cluster NDB 7.2.1 (`NDB$EPOCH()` and `NDB$EPOCH_TRANS()`) compare the order in which epochs are replicated. Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

Important

Conflict resolution as described in this section is always applied on a row-by-row basis rather than a transactional basis. In addition, it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements. Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:

- On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` [2372] (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see [The `ndb_replication` system table](#)).

Note

If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet` [519].

See [Section 16.4.1.19, “Replication and `max_allowed_packet`”](#), for more information about this issue.

- On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see [The `ndb_replication` system table](#)).

- Prior to MySQL Cluster NDB 7.2.5, conflict detection and resolution did not always work properly unless set up for NDB tables created on the same server only (Bug #13578660).

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never `TIMESTAMP`; instead, its data type should be `INT` (`INTEGER`) or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

The `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary MySQL Cluster, and do not make use of timestamps.

Master column control. We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master’s binary log. This is done with the `--ndb-log-update-as-write` [2373] option for `mysqld`, as described later in this section.

Important

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

Logging Full or Partial Rows (`--ndb-log-updated-only` Option)

| | |
|----------------------------|-------------------------------------|
| Command-Line Format | <code>--ndb-log-updated-only</code> |
| Option-File Format | <code>ndb_log_updated_only</code> |
| Variable Name | <code>ndb_log_updated_only</code> |
| Variable Scope | Global |
| Dynamic Variable | Yes |
| | Permitted Values |
| | Type <code>boolean</code> |
| | Default <code>ON</code> |

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to `0` or `OFF`.

`--ndb-log-update-as-write` [2373] Option: Logging Changed Data as Updates

| | |
|----------------------------|--|
| Command-Line Format | <code>--ndb-log-update-as-write</code> |
| Option-File Format | <code>ndb-log-update-as-write</code> |
| Variable Name | <code>ndb_log_update_as_write</code> |

| | | |
|-------------------------|-------------------------|---------|
| Variable Scope | Global | |
| Dynamic Variable | Yes | |
| | Permitted Values | |
| | Type | boolean |
| | Default | ON |

The setting of the MySQL Server's `--ndb-log-update-as-write` [2373] option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.) To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

Conflict resolution control. Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

The `ndb_replication` system table. To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
  PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the next few paragraphs.

db. The name of the database containing the table to be replicated.

table_name. The name of the table to be replicated.

server_id. The unique server ID of the MySQL instance (SQL node) where the table resides.

binlog_type. The type of binary logging to be employed. This is determined as shown in the following table:

| Value | Internal Value | Description |
|-------|-------------------------------|---|
| 0 | <code>NBT_DEFAULT</code> | Use server default |
| 1 | <code>NBT_NO_LOGGING</code> | Do not log this table in the binary log |
| 2 | <code>NBT_UPDATED_ONLY</code> | Only updated attributes are logged |

| Value | Internal Value | Description |
|-------|--|--|
| 3 | NBT_FULL | Log full row, even if not updated (MySQL server default behavior) |
| 4 | NBT_USE_UPDATE | (For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only—not intended for separate use) |
| 5 | [Not used] | --- |
| 6 | NBT_UPDATED_ONLY_USE_UPDATE (equal to NBT_UPDATED_ONLY NBT_USE_UPDATE) | Use updated attributes, even if values are unchanged |
| 7 | NBT_FULL_USE_UPDATE (equal to NBT_FULL NBT_USE_UPDATE) | Use full row, even if values are unchanged |

conflict_fn. The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- NDB\$OLD(*column_name*)
- NDB\$MAX(*column_name*)
- NDB\$MAX_DELETE_WIN(*column_name*)
- NDB\$EPOCH() (MySQL Cluster NDB 7.2.1 and later)
- NDB\$EPOCH_TRANS() (MySQL Cluster NDB 7.2.1 and later)
- NULL

These functions are described in the next few paragraphs.

NDB\$OLD(*column_name*). If the value of *column_name* is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```
if (master_old_column_value == slave_current_column_value)
    apply_update();
else
    log_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

Important

The column value from the master's “before” image is used by this function.

NDB\$MAX(*column_name*). If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```
if (master_new_column_value > slave_current_column_value)
    apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

**Important**

The column value from the master's “after” image is used by this function.

`NDB$MAX_DELETE_WIN(column_name)`. This is a variation on `NDB$MAX()`. Due to the fact that no timestamp is available for a delete operation, a delete using `NDB$MAX()` is in fact processed as `NDB$OLD`. However, for some use cases, this is not optimal. For `NDB$MAX_DELETE_WIN()`, if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```
if ( (master_new_column_value > slave_current_column_value)
    ||
    operation.type == "delete" )
    apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

**Note**

As with `NDB$MAX()`, the column value from the master's “after” image is the value used by this function.

`NDB$EPOCH()`. The `NDB$EPOCH()` function, available beginning with MySQL Cluster NDB 7.2.1, tracks the order in which replicated epochs are applied on a slave MySQL Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of `NDB$EPOCH()` also applies to `NDB$EPOCH_TRANS()`. Any exceptions are noted in the text.

`NDB$EPOCH()` is asymmetric, operating on one MySQL Cluster in a two-cluster circular replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible for detecting and handling conflicts, while the slave on the secondary is not involved in any conflict detection or handling.

When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary MySQL Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary MySQL Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.

- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.
- Assuming a period of sufficient length without any conflicts, all data on the secondary MySQL Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than

```
CEIL( LOG2( TimeBetweenGlobalCheckpoints [2065] / TimeBetweenEpochs [2065] ), 1)
```

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints` [2065], `TimeBetweenEpochs` [2065], or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exception table schema rules as described elsewhere in this section (see `NDB$OLD(column_name)`). Note that you need to create any exception table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are activated by including relevant entries in the `mysql.ndb_replication` table (see [The ndb_replication system table](#)). The roles of the primary and secondary MySQL Clusters in this scenario are fully determined by `mysql.ndb_replication` table entries.

Note

Because the conflict detection algorithms employed by `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are asymmetric, you must use different values for the primary slave's and secondary slave's `server_id` entries.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` status variables. MySQL Cluster NDB 7.2.1 introduces several status variables that can be used to monitor `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this slave was last restarted from the current value of the `Ndb_conflict_fn_epoch` [2172] system status variable.

`Ndb_conflict_fn_epoch_trans` [2172] provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`; the number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count` [2173].

For more information, see [Section 17.3.4.4, “MySQL Cluster Status Variables”](#).

Limitations on `NDB$EPOCH()`. The following limitations currently apply when using `NDB$EPOCH()` to perform conflict detection:

- Conflicts are detected using MySQL Cluster epoch boundaries, with granularity proportional to `TimeBetweenEpochs` [2065] (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to $2 * (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})$. This implies that—assuming the default for `TimeBetweenEpochs` [2065] and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window

size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.
- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two MySQL Clusters in a circular “active-active” configuration are currently supported when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` for conflict detection.
- Tables having `BLOB` or `TEXT` columns are not currently supported with `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`.

`NDB$EPOCH_TRANS()`. `NDB$EPOCH_TRANS()` extends the `NDB$EPOCH()` function, and, like `NDB$EPOCH()`, is available beginning with MySQL Cluster NDB 7.2.1. Conflicts are detected and handled in the same way using the “primary wins all” rule (see `NDB$EPOCH()`) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where `NDB$EPOCH()` realigns individual conflicting rows on the secondary, `NDB$EPOCH_TRANS()` realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster’s binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

`NDB$EPOCH_TRANS()` is subject to the same conditions and limitations as `NDB$EPOCH()`, and in addition requires that Version 2 binary log row events are used (`--log-bin-use-v1-row-events` [1893] equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all transaction IDs must be recorded in the secondary’s binary log (`--ndb-log-transaction-id` [2143] option), which adds a further variable overhead (up to 13 bytes per row).

See `NDB$EPOCH()`.

NULL. Indicates that conflict resolution is not to be used for the corresponding table.

Status information. A server status variable `Ndb_conflict_fn_max` [2172] provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old` [2172]. In addition to incrementing `Ndb_conflict_fn_old` [2172], the primary key of the row that was not used is inserted into an *exceptions table*, as explained later in this section.

Exceptions table. To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()` in MySQL Cluster NDB 7.2.1 and later. The name of this table is that of the table for which conflict resolution is to be applied,

with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exception table name should be `mytable$EX`.) This table is created as follows:

```
CREATE TABLE original_table$EX (
  server_id INT UNSIGNED,
  master_server_id INT UNSIGNED,
  master_epoch BIGINT UNSIGNED,
  count INT UNSIGNED,
  original_table_pk_columns,
  [additional_columns,]
  PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

The first four columns are required. Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table.

Note

The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id` [551], `master_server_id`, `master_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

The data types for the columns duplicating the primary key columns of the original table should be the same as for (or larger than) the original columns.

Additional columns may optionally be defined following these columns, but not before any of them; any such extra columns cannot be `NOT NULL`. The exception table's primary key must be defined as shown. The exception table must use the `NDB` storage engine. An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.

Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

Examples. The following examples assume that you have already a working MySQL Cluster replication setup, as described in [Section 17.6.5, “Preparing the MySQL Cluster for Replication”](#), and [Section 17.6.6, “Starting MySQL Cluster Replication \(Single Replication Channel\)”](#).

- **`NDB$MAX()` example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:
 1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.
 2. On the master, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` [551] indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
  columns
  mycol INT UNSIGNED,
  columns
) ENGINE=NDB;
```

Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the slave.

Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE`—should be used to control logging on the master using the `ndb_replication` table rather than by using command-line options.

- **`NDB$OLD()` example.** Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```
CREATE TABLE test.t2 (
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  columns,
  mycol INT UNSIGNED NOT NULL,
  columns,
  PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX (
  server_id SMALLINT UNSIGNED,
  master_server_id INT UNSIGNED,
  master_epoch BIGINT UNSIGNED,
  count BIGINT UNSIGNED,
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  [additional_columns,]
  PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using [NDB \\$OLD\(\)](#). For each such table, there must be a corresponding row in [mysql.ndb_replication](#), and there must be an exceptions table in the same database as the table being replicated.

17.7. MySQL Cluster Release Notes

MySQL Cluster release notes are no longer published in the MySQL Reference Manual.

Release notes for the changes in each release of MySQL Cluster are located at [MySQL Cluster 7.2 Release Notes](#).

Chapter 18. Partitioning

Table of Contents

| | |
|---|------|
| 18.1. Overview of Partitioning in MySQL | 2383 |
| 18.2. Partitioning Types | 2385 |
| 18.2.1. RANGE Partitioning | 2387 |

| 18.3.4. Obtaining Information About Partitions | 2422 |
| 18.4. Partition Pruning | 2424 |
| 18.5. Restrictions and Limitations on Partitioning | 2427 |
| 18.5.1. Partitioning Keys, Primary Keys, and Unique Keys | 2433 |
| 18.5.2. Partitioning Limitations Relating to Storage Engines | 2437 |
| 18.5.3. Partitioning Limitations Relating to Functions | 2437 |
| 18.5.4. Partitioning and Table-Level Locking | 2438 |

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by means of a [SHOW VARIABLES](#) statement such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';

+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_partitioning | YES |
+-----+-----+
1 row in set (0.00 sec)
```

You can also check the output of the [SHOW PLUGINS](#) statement, as shown here:

```
mysql> SHOW PLUGINS;

+-----+-----+-----+-----+-----+
| Name      | Status | Type          | Library | License |
+-----+-----+-----+-----+-----+
| binlog    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| partition | ACTIVE | STORAGE ENGINE | NULL   | GPL   |
| ARCHIVE   | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| CSV       | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| InnoDB    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| MyISAM    | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster | DISABLED | STORAGE ENGINE | NULL    | GPL     |
+-----+-----+-----+-----+-----+
11 rows in set (0.00 sec)
```

If you do not see the `have_partitioning` [504] variable with the value `YES` listed in the output of an appropriate `SHOW VARIABLES` statement, or if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output of `SHOW PLUGINS` (show in bold text in the example just given), then your version of MySQL was not built with partitioning support.

MySQL 5.5 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in commercial MySQL Server binaries, see *MySQL Enterprise Server 5.1* on the MySQL Web site at <http://www.mysql.com/products/enterprise/server.html>.

To enable partitioning if you are compiling MySQL 5.5 from source, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see [Section 2.10, “Installing MySQL from Source”](#).

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` [462] option, in which case the value of `have_partitioning` [504] is `DISABLED`. However, if you do this, you cannot access any partitioned tables until the server is once again restarted without the `--skip-partition` [462] option.

An introduction to partitioning and partitioning concepts may be found in [Section 18.1, “Overview of Partitioning in MySQL”](#).

MySQL supports several types of partitioning, which are discussed in [Section 18.2, “Partitioning Types”](#), as well as subpartitioning, which is described in [Section 18.2.6, “Subpartitioning”](#).

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in [Section 18.3, “Partition Management”](#).

Table maintenance commands for use with partitioned tables are discussed in [Section 18.3.3, “Maintenance of Partitions”](#).

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 20.12, “The INFORMATION_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 18.2.7, “How MySQL Partitioning Handles NULL”](#).

For known issues with partitioning in MySQL 5.5, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#).

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.5 binaries are available from <http://dev.mysql.com/downloads/mysql/5.5.html>. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see [Section 2.10, “Installing MySQL from Source”](#). If you have problems compiling a partitioning-enabled MySQL 5.5 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

18.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.5.

For information on partitioning restrictions and feature limitations, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the [InnoDB](#) storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 8.11.3.1, “Using Symbolic Links”](#), for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of [RANGE](#), [LIST](#), and [\[LINEAR\] HASH](#) partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either [NULL](#) or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

([MAXVALUE](#) is used to represent the least upper bound for the type of integer in question. [-MAXVALUE](#) represents the greatest lower bound.)

For [\[LINEAR\] KEY](#), [RANGE COLUMNS](#), and [LIST COLUMNS](#) partitioning, the partitioning expression consists of a list of one or more columns.

For [\[LINEAR\] KEY](#) partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see [Section 18.2, “Partitioning Types”](#), as well as [Section 13.1.17, “CREATE TABLE Syntax”](#), which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see [Section 18.5.3, “Partitioning Limitations Relating to Functions”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.5 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.5.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see [Chapter 18, Partitioning](#).

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.5, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use [MyISAM](#) for one partition and [InnoDB](#) for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the [MERGE](#), [CSV](#), or [FEDERATED](#) storage engines.

Partitioning by [KEY](#) or [LINEAR KEY](#) is possible with [NDBCLUSTER](#), but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an [NDBCLUSTER](#) table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the [PARTITION BY KEY](#) or [PARTITION BY LINEAR KEY](#) clause of the [CREATE TABLE](#) or [ALTER TABLE](#) statement used to create or modify a user-partitioned [NDBCLUSTER](#) table, then the table is not required to have an explicit primary key. For more information, see [Section 17.1.6.1, “Noncompliance with SQL Syntax in MySQL Cluster”](#).

To employ a particular storage engine for a partitioned table, it is necessary only to use the [\[STORAGE\] ENGINE](#) option just as you would for a nonpartitioned table. However, you should keep in mind that [\[STORAGE\] ENGINE](#) (and other table options) need to be listed *before* any partitioning options are used in a [CREATE TABLE](#) statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the [InnoDB](#) storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

Each [PARTITION](#) clause can include a [\[STORAGE\] ENGINE](#) option, but in MySQL 5.5 this has no effect.

Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options for the [PARTITION](#) clause of the [CREATE TABLE](#) statement used to create the partitioned table.

The [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options have no effect when defining partitions for tables using the [InnoDB](#) storage engine.

[DATA DIRECTORY](#) and [INDEX DIRECTORY](#) are not supported for individual partitions or subpartitions on Windows. These options are ignored on Windows, except that a warning is generated.

In addition, [MAX_ROWS](#) and [MIN_ROWS](#) can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The [MAX_ROWS](#) option can be useful for causing MySQL Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes.

See the documentation for the [DataMemory \[2043\]](#) data node configuration parameter, as well as [Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see [Section 18.4, “Partition Pruning”](#).

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` [\[1206\]](#) and `COUNT()` [\[1204\]](#) can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;` By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as MySQL Partitioning development continues.

18.2. Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.5. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 18.2.1, “RANGE Partitioning”](#). MySQL 5.5 adds an extension, `RANGE COLUMNS`, to this type. See [Section 18.2.3.1, “RANGE COLUMNS partitioning”](#).
- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 18.2.2, “LIST Partitioning”](#). MySQL 5.5 adds an extension, `LIST COLUMNS`, to this type. See [Section 18.2.3.2, “LIST COLUMNS partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See [Section 18.2.4, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See [Section 18.2.5, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.5. However, it is not difficult in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 5.5, it is also possible to use a [DATE](#) or [DATETIME](#) column as the partitioning column using [RANGE COLUMNS](#) and [LIST COLUMNS](#) partitioning.

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or [NULL](#). If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- [Section 18.2.1](#), “[RANGE Partitioning](#)”
- [Section 18.2.4](#), “[HASH Partitioning](#)”
- [Section 18.2.4.1](#), “[LINEAR HASH Partitioning](#)”

For more complex examples of date-based partitioning, see the following sections:

- [Section 18.4](#), “[Partition Pruning](#)”
- [Section 18.2.6](#), “[Subpartitioning](#)”

MySQL partitioning is optimized for use with the [TO_DAYS\(\)](#) [1148], [YEAR\(\)](#) [1152], and [TO_SECONDS\(\)](#) [1149] functions. However, you can use other date and time functions that return an integer or [NULL](#), such as [WEEKDAY\(\)](#) [1152], [DAYOFYEAR\(\)](#) [1140], or [MONTH\(\)](#) [1143]. See [Section 12.7](#), “[Date and Time Functions](#)”, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the [RANGE](#) and [LIST](#) partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For [HASH](#) partitioning, the user function employed must return an integer value greater than 0. For [KEY](#) partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following [CREATE TABLE](#) statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->     PARTITION mypart VALUES IN (1,3,5),
->     PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 13.1.17](#), “[CREATE TABLE Syntax](#)”.

18.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the [VALUES LESS THAN](#) operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a [PARTITION BY RANGE](#) clause as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
```

```

PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);

```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

Note

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 18.2.2, “LIST Partitioning”](#). Also see [Section 13.2.5, “INSERT Syntax”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 18.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',

```

```

    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)` [1152]. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` [1150] function, as shown in this example:

```

CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 18.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 18.4, “Partition Pruning”](#), for more information about how this is accomplished.

A variant on this type of partitioning, `RANGE COLUMNS` partitioning, was introduced in MySQL 5.5.0. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See [Section 18.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

Partitioning schemes based on time intervals. If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 5.5, you have two options:

1. Partition the table by `RANGE`, and for the partitioning expression, employ a function operating on a `DATE`, `TIME`, or `DATETIME` column and returning an integer value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Beginning with MySQL 5.5.1, it is also possible to partition a table by `RANGE` based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP () [1150]` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
  report_id INT NOT NULL,
  report_status VARCHAR(20) NOT NULL,
  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
  PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
  PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
  PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
  PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
  PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
```

```

PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

Also beginning with MySQL 5.5.1, any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Note

It is also possible in MySQL 5.5.1 and later to use `UNIX_TIMESTAMP(timestamp_column)` [1150] as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

- Partition the table by `RANGE COLUMNS`, using a `DATE` or `DATETIME` column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```

CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE COLUMNS(joined) (
  PARTITION p0 VALUES LESS THAN ('1960-01-01'),
  PARTITION p1 VALUES LESS THAN ('1970-01-01'),
  PARTITION p2 VALUES LESS THAN ('1980-01-01'),
  PARTITION p3 VALUES LESS THAN ('1990-01-01'),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

Note

The use of partitioning columns employing date or time types other than `DATE` or `DATETIME` is not supported with `RANGE COLUMNS`.

18.2.2. LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

Note

In MySQL 5.5, it is possible to match against only a list of integers (and possibly `NULL`—see Section 18.2.7, “How MySQL Partitioning Handles `NULL`”) when partitioning by `LIST`.

However, beginning with MySQL 5.5.0, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.17, “`CREATE TABLE Syntax`”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 18.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

| Region | Store ID Numbers |
|---------|----------------------|
| North | 3, 5, 6, 9, 17 |
| East | 1, 2, 10, 11, 19, 20 |
| West | 4, 12, 13, 14, 18 |
| Central | 7, 8, 15, 16 |

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LIST(store_id) (
  PARTITION pNorth VALUES IN (3,5,6,9,17),
  PARTITION pEast VALUES IN (1,2,10,11,19,20),
  PARTITION pWest VALUES IN (4,12,13,14,18),
  PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. Beginning with MySQL 5.5.0, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);` (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with [RANGE](#) partitioning, it is possible to combine [LIST](#) partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 18.2.6, “Subpartitioning”](#).

Unlike the case with [RANGE](#) partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
->   c1 INT,
->   c2 INT
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (1, 4, 7),
->   PARTITION p1 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not:

```
mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT INTO h2 VALUES (4, 7), (3, 5), (6, 0);
ERROR 1525 (HY000): Table has no partition for value 3
mysql> SELECT * FROM h2;
+-----+-----+
| c1   | c2   |
+-----+-----+
|    4 |    7 |
+-----+-----+
1 row in set (0.00 sec)
```

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1   | c2   |
+-----+-----+
|    7 |    5 |
|    1 |    9 |
|    2 |    5 |
+-----+-----+
3 rows in set (0.00 sec)
```

MySQL 5.5 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use multiple columns as partitioning keys. For more information, see [Section 18.2.3.2, “LIST COLUMNS partitioning”](#).

18.2.3. COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on `RANGE` and `LIST` partitioning that were introduced in MySQL 5.5.0. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in

partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both [RANGE COLUMNS](#) partitioning and [LIST COLUMNS](#) partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: [TINYINT](#), [SMALLINT](#), [MEDIUMINT](#), [INT \(INTEGER\)](#), and [BIGINT](#). (This is the same as with partitioning by [RANGE](#) and [LIST](#).)

Other numeric data types (such as [DECIMAL](#) or [FLOAT](#)) are not supported as partitioning columns.

- [DATE](#) and [DATETIME](#).

Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: [CHAR](#), [VARCHAR](#), [BINARY](#), and [VARBINARY](#).

[TEXT](#) and [BLOB](#) columns are not supported as partitioning columns.

The discussions of [RANGE COLUMNS](#) and [LIST COLUMNS](#) partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see [Section 18.2.1, “RANGE Partitioning”](#), and [Section 18.2.2, “LIST Partitioning”](#), respectively.

18.2.3.1. RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

[RANGE COLUMNS](#) partitioning differs significantly from [RANGE](#) partitioning in the following ways:

- [RANGE COLUMNS](#) does not accept expressions, only names of columns.
- [RANGE COLUMNS](#) accepts a list of one or more columns.

[RANGE COLUMNS](#) partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in [RANGE COLUMNS](#) partitions is also based on comparisons between tuples; this is discussed further later in this section.

- [RANGE COLUMNS](#) partitioning columns are not restricted to integer columns; string, [DATE](#) and [DATETIME](#) columns can also be used as partitioning columns. (See [Section 18.2.3, “COLUMNS Partitioning”](#), for details.)

The basic syntax for creating a table partitioned by [RANGE COLUMNS](#) is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
  PARTITION partition_name VALUES LESS THAN (value_list)[,
  PARTITION partition_name VALUES LESS THAN (value_list)[,
  ...]
)

column_list:
  column_name[, column_name][, ...]

value_list:
  value[, value][, ...]
```

**Note**

Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see [Section 13.1.17, “CREATE TABLE Syntax”](#).

In the syntax just shown, *column_list* is a list of one or more columns (sometimes called a *partitioning column list*), and *value_list* is a list of values (that is, it is a *partition definition value list*). A *value_list* must be supplied for each partition definition, and each *value_list* must have the same number of values as the *column_list* has columns. Generally speaking, if you use *N* columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of *N* values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
->   a INT,
->   b INT,
->   c CHAR(3),
->   d INT
-> )
-> PARTITION BY RANGE COLUMNS(a,d,c) (
->   PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
->   PARTITION p1 VALUES LESS THAN (10,20,'mmmm'),
->   PARTITION p2 VALUES LESS THAN (15,30,'sss'),
->   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form `(INT, INT, CHAR(3))`, which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
  a INT,
  b INT
)
PARTITION BY RANGE (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'r1';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              |            0 |
| p1              |            3 |
+-----+-----+
2 rows in set (0.00 sec)
```

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```
CREATE TABLE rc1 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
  PARTITION p0 VALUES LESS THAN (5, 12),
  PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rc1';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p              | p0              |            2 |
| p              | p1              |            1 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----+-----+-----+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----+-----+-----+
| 1                | 1                | 0                |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see [Section 13.2.10.5, “Row Subqueries”](#).

For a table partitioned by `RANGE COLUMNS` using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by `RANGE`. The following `CREATE TABLE` statement creates a table partitioned by `RANGE COLUMNS` using 1 partitioning column:

```
CREATE TABLE rx (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows `(5,10)`, `(5,11)`, and `(5,12)` into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rx';
```

| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
|--------------|----------------|------------|
| p | p0 | 0 |
| p | p1 | 3 |

```
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by `RANGE COLUMNS` where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc2 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

```
CREATE TABLE rc3 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
```

```

PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:

```

CREATE TABLE rc4 (
  a INT,
  b INT,
  c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
  PARTITION p0 VALUES LESS THAN (0,25,50),
  PARTITION p1 VALUES LESS THAN (10,20,100),
  PARTITION p2 VALUES LESS THAN (10,30,50)
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);

```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```

mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)

```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```

mysql> CREATE TABLE rcf (
->   a INT,
->   b INT,
->   c INT
-> )
-> PARTITION BY RANGE COLUMNS(a,b,c) (
->   PARTITION p0 VALUES LESS THAN (0,25,50),
->   PARTITION p1 VALUES LESS THAN (20,20,100),
->   PARTITION p2 VALUES LESS THAN (10,30,50),
->   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition

```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```

mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)

```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See [Section 18.2.3, “COLUMNS Partitioning”](#), for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee’s last name, like this:

```
CREATE TABLE employees_by_lname (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Note

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, `'and'` sorts before `'Andersen'`, but when using a collation that is case insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see [Section 10.1, “Character Set Support”](#).

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) (
```

```

PARTITION p0 VALUES LESS THAN ('1970-01-01'),
PARTITION p1 VALUES LESS THAN ('1980-01-01'),
PARTITION p2 VALUES LESS THAN ('1990-01-01'),
PARTITION p3 VALUES LESS THAN ('2000-01-01'),
PARTITION p4 VALUES LESS THAN ('2010-01-01'),
PARTITION p5 VALUES LESS THAN (MAXVALUE)
);

```

See [Section 13.1.17, “CREATE TABLE Syntax”](#), for additional information about `PARTITION BY RANGE COLUMNS` syntax.

18.2.3.2. LIST COLUMNS partitioning

MySQL 5.5 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see [Section 18.2.3, “COLUMNS Partitioning”](#).)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

| Region | Cities |
|--------|--------------------------------|
| 1 | Oskarshamn, Högsby, Mönsterås |
| 2 | Vimmerby, Hultsfred, Västervik |
| 3 | Nässjö, Eksjö, Vetlanda |
| 4 | Uppvidinge, Alvesta, Växjö |

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```

CREATE TABLE customers_1 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
  PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
  PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
  PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
  PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjö')
);

```

As with partitioning by `RANGE COLUMNS`, you do not need to use expressions in the `COLUMNS()` clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with `COLUMNS()`.)

It is also possible to use `DATE` and `DATETIME` columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs `LIST COLUMNS` partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```

CREATE TABLE customers_2 (
  first_name VARCHAR(25),

```

```

    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
    PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
    '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
    PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
    '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
    PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
    '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
    PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
    '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);

```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ [RANGE](#) or [RANGE COLUMNS](#) partitioning instead. In this case, since the column we wish to use as the partitioning key is a [DATE](#) column, we use [RANGE COLUMNS](#) partitioning, as shown here:

```

CREATE TABLE customers_3 (
    first_name VARCHAR(25),
    last_name VARCHAR(25),
    street_1 VARCHAR(30),
    street_2 VARCHAR(30),
    city VARCHAR(15),
    renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
    PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
    PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
    PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
    PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);

```

See [Section 18.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

In addition (as with [RANGE COLUMNS](#) partitioning), you can use multiple columns in the [COLUMNS\(\)](#) clause.

See [Section 13.1.17, “CREATE TABLE Syntax”](#), for additional information about [PARTITION BY LIST COLUMNS\(\)](#) syntax.

18.2.4. HASH Partitioning

Partitioning by [HASH](#) is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using [HASH](#) partitioning, it is necessary to append to the [CREATE TABLE](#) statement a [PARTITION BY HASH \(expr\)](#) clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a [PARTITIONS num](#) clause, where *num* is a positive integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

`expr` must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 18.5, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` [1148] is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` [1152] with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)` [1148], because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)` [1152]. Even so, `YEAR(date_col)` [1152] is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)` [1152].

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6` [1128]. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by widely different changes in the value of the expression. For example, changing `int_col` from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of `int_col` from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation $y=cx$ where c is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of num partitions to use based on the modulus of the result of the user function. In other words, for an expression $expr$, the partition in which the record is stored is partition number N , where $N = \text{MOD}(expr, num)$. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.5 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 18.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

Note

If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s `column_list` must be part of that key.

18.2.4.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that *num* is 13. Then `LOG(2, 13)` [1126] is 3.7004397181411. `CEILING(3.7004397181411)` [1125] is 4, and `V = POWER(2, 4)` [1128], which is 16.)

2. Set $N = F(\text{column_list}) \& (V - 1)$.

3. While $N \geq \text{num}$:

- Set $V = \text{CEIL}(V / 2)$
- Set $N = N \& (V - 1)$

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6
(6 >= 6 is TRUE: additional step required)
N = 6 & CEILING(8 / 2)
  = 6 & 3
  = 2
(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

18.2.5. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` [1187] for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()` [1188].

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.5:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tm1 (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 18.5, “Restrictions and Limitations on Partitioning”](#).

Note

Tables using the `NDBCLUSTER` storage engine are implicitly partitioned by `KEY`, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDBCLUSTER` storage engine for each MySQL Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an `NDBCLUSTER` table, the table must have an explicit primary key, and any columns used in the partitioning

expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for MySQL Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 17, MySQL Cluster NDB 7.2](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
  col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 18.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

18.2.6. Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into $3 * 2 = 6$ partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.5, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column

used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
      SUBPARTITION s2,
      SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s4,
      SUBPARTITION s5
    )
  );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s2,
      SUBPARTITION s3
    )
  );
```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.5:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
```

Subpartitioning

```
        SUBPARTITION s2,  
        SUBPARTITION s3  
    ),  
    PARTITION p2 VALUES LESS THAN MAXVALUE (  
        SUBPARTITION s4,  
        SUBPARTITION s5  
    )  
);
```

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)  
PARTITION BY RANGE( YEAR(purchased) )  
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (  
    PARTITION p0 VALUES LESS THAN (1990) (  
        SUBPARTITION s0  
            DATA DIRECTORY = '/disk0/data'  
            INDEX DIRECTORY = '/disk0/idx',  
        SUBPARTITION s1  
            DATA DIRECTORY = '/disk1/data'  
            INDEX DIRECTORY = '/disk1/idx'  
    ),  
    PARTITION p1 VALUES LESS THAN (2000) (  
        SUBPARTITION s2  
            DATA DIRECTORY = '/disk2/data'  
            INDEX DIRECTORY = '/disk2/idx',  
        SUBPARTITION s3  
            DATA DIRECTORY = '/disk3/data'  
            INDEX DIRECTORY = '/disk3/idx'  
    ),  
    PARTITION p2 VALUES LESS THAN MAXVALUE (  
        SUBPARTITION s4  
            DATA DIRECTORY = '/disk4/data'  
            INDEX DIRECTORY = '/disk4/idx',  
        SUBPARTITION s5  
            DATA DIRECTORY = '/disk5/data'  
            INDEX DIRECTORY = '/disk5/idx'  
    )  
);
```

In this case, a separate disk is used for the data and for the indexes of each [RANGE](#). Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)  
PARTITION BY RANGE(YEAR(purchased))  
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (  
    PARTITION p0 VALUES LESS THAN (1990) (  
        SUBPARTITION s0a  
            DATA DIRECTORY = '/disk0'  
            INDEX DIRECTORY = '/disk1',  
        SUBPARTITION s0b  
            DATA DIRECTORY = '/disk2'  
            INDEX DIRECTORY = '/disk3'  
    ),  
    PARTITION p1 VALUES LESS THAN (2000) (  
        SUBPARTITION s1a  
            DATA DIRECTORY = '/disk4/data'  
            INDEX DIRECTORY = '/disk4/idx',  
        SUBPARTITION s1b  
            DATA DIRECTORY = '/disk5/data'  
            INDEX DIRECTORY = '/disk5/idx'  
    ),  
    PARTITION p2 VALUES LESS THAN MAXVALUE (  
        SUBPARTITION s2a,
```

```

        SUBPARTITION s2b
    )
);

```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
 - The data for subpartition `s0a` is stored on `/disk0`.
 - The indexes for subpartition `s0a` are stored on `/disk1`.
 - The data for subpartition `s0b` is stored on `/disk2`.
 - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
 - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.
 - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 18.3, “Partition Management”](#), for an explanation of how this can be done.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` [614] server SQL mode is in effect. Beginning with MySQL 5.5.5, these options are also not permitted when defining subpartitions (Bug #42954).

18.2.7. How MySQL Partitioning Handles `NULL`

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

Handling of `NULL` with `RANGE` partitioning. If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
```

Query OK, 0 rows affected (0.09 sec)

```
mysql> CREATE TABLE t2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (-5),
->   PARTITION p1 VALUES LESS THAN (0),
->   PARTITION p2 VALUES LESS THAN (10),
->   PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
```

Query OK, 0 rows affected (0.09 sec)

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| t1 | p0 | 0 | 0 | 0 |
| t1 | p1 | 0 | 0 | 0 |
| t1 | p2 | 0 | 0 | 0 |
| t2 | p0 | 0 | 0 | 0 |
| t2 | p1 | 0 | 0 | 0 |
| t2 | p2 | 0 | 0 | 0 |
| t2 | p3 | 0 | 0 | 0 |

7 rows in set (0.00 sec)

(For more information about this table, see [Section 20.12, “The `INFORMATION_SCHEMA PARTITIONS Table`”](#).) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM t1;
+-----+-----+
| id  | name  |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SELECT * FROM t2;
+-----+-----+
| id  | name  |
+-----+-----+
| NULL | mothra |
+-----+-----+
```

```
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| t1 | p0 | 1 | 20 | 20 |
| t1 | p1 | 0 | 0 | 0 |
| t1 | p2 | 0 | 0 | 0 |
| t2 | p0 | 1 | 20 | 20 |
| t2 | p1 | 0 | 0 | 0 |
| t2 | p2 | 0 | 0 | 0 |
| t2 | p3 | 0 | 0 | 0 |

```
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 13.1.7, “ALTER TABLE Syntax”](#).)

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) )(
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` [1152] returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

Handling of `NULL` with `LIST` partitioning. A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
-> c1 INT,
```

```

->     c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->     PARTITION p0 VALUES IN (0, 3, 6),
->     PARTITION p1 VALUES IN (1, 4, 7),
->     PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL

```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```

mysql> CREATE TABLE ts2 (
->     c1 INT,
->     c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->     PARTITION p0 VALUES IN (0, 3, 6),
->     PARTITION p1 VALUES IN (1, 4, 7),
->     PARTITION p2 VALUES IN (2, 5, 8),
->     PARTITION p3 VALUES IN (NULL)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
->     c1 INT,
->     c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->     PARTITION p0 VALUES IN (0, 3, 6),
->     PARTITION p1 VALUES IN (1, 4, 7, NULL),
->     PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```

mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';

```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| ts2 | p0 | 0 | 0 | 0 |
| ts2 | p1 | 0 | 0 | 0 |

```

| ts2      | p2      |          0 |          0 |          0 |
| / ts2    | / p3    | /          1 /          20 /          20 /
| ts3      | p0      |          0 |          0 |          0 |
| / ts3    | / p1    | /          1 /          20 /          20 /
| ts3      | p2      |          0 |          0 |          0 |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)

```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

Handling of `NULL` with `HASH` and `KEY` partitioning. `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```

mysql> CREATE TABLE th (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)

```

The partitions belonging to this table can be viewed using the query shown here:

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th          | p0             |          0 |          0     |          0   |
| th          | p1             |          0 |          0     |          0   |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```

mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+-----+-----+
| c1   | c2   |
+-----+-----+
| NULL | mothra |
+-----+-----+
| 0    | gigan  |
+-----+-----+
2 rows in set (0.01 sec)

```

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+

```

```

+-----+-----+-----+-----+-----+
| th      | p0      |      2 |      20 |      20 |
| th      | p1      |      0 |      0  |      0  |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

18.3. Partition Management

MySQL 5.5 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 18.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 18.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 18.3.4, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.5 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 18.3.3, “Maintenance of Partitions”](#).

Note

In MySQL 5.5, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```

CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (2000),
    PARTITION p3 VALUES LESS THAN (2005)
);

```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```

ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;

```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 13.1.7, “ALTER TABLE Syntax”](#).

**Important**

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITIONS`).

Beginning with MySQL 5.5.0, it is possible to delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

18.3.1. Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 18.3.2, “Management of HASH and KEY Partitions”](#). Dropping a RANGE or LIST partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either RANGE or by LIST can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
->     PARTITION BY RANGE( YEAR(purchased) ) (
->         PARTITION p0 VALUES LESS THAN (1990),
->         PARTITION p1 VALUES LESS THAN (1995),
->         PARTITION p2 VALUES LESS THAN (2000),
->         PARTITION p3 VALUES LESS THAN (2005)
->     );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
->     (1, 'desk organiser', '2003-10-15'),
->     (2, 'CD player', '1993-11-05'),
->     (3, 'TV set', '1996-03-10'),
->     (4, 'bookcase', '1982-01-10'),
->     (5, 'exercise bike', '2004-05-09'),
->     (6, 'sofa', '1987-06-05'),
->     (7, 'popcorn maker', '2001-11-22'),
->     (8, 'aquarium', '1992-08-04'),
->     (9, 'study desk', '1984-09-16'),
->     (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
->     WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id   | name      | purchased |
+-----+-----+-----+
| 3    | TV set    | 1996-03-10 |
| 10   | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
```

Query OK, 0 rows affected (0.03 sec)

Note

The `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, you must have the `DROP` [\[696\]](#) privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See [Section 13.1.33](#), “`TRUNCATE TABLE Syntax`”).

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 13.1.7](#), “`ALTER TABLE Syntax`”, for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
      Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id  | name          | purchased |
+-----+-----+-----+
| 11  | pencil holder | 1995-07-12 |
| 1   | desk organiser | 2003-10-15 |
| 5   | exercise bike | 2004-05-09 |
| 7   | popcorn maker | 2001-11-22 |
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
```

```
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
      -> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of [ALTER TABLE ... DROP PARTITION](#) is not reported by the server as it would be by the equivalent [DELETE](#) query.

Dropping [LIST](#) partitions uses exactly the same [ALTER TABLE ... DROP PARTITION](#) syntax as used for dropping [RANGE](#) partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 18.2.2, “LIST Partitioning”](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the [ALTER TABLE ... ADD PARTITION](#) statement. For tables which are partitioned by [RANGE](#), this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970),
  PARTITION p1 VALUES LESS THAN (1980),
  PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990 to 1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

Important

With tables that are partitioned by range, you can use [ADD PARTITION](#) to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```
mysql> ALTER TABLE members
      > ADD PARTITION (
      > PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
      increasing for each partition
```

In a similar fashion, you can add new partitions to a table that is partitioned by [LIST](#). Suppose a table `tt` is defined using the following [CREATE TABLE](#) statement:

```
CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
```

```
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new [LIST](#) partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving [RANGE](#) partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
```

```
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` [1152] is less than 1960 and `s1` contains those rows in which `YEAR(dob)` [1152] is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE` (see [Section 13.1.17, “CREATE TABLE Syntax”](#)). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The [PARTITION](#) clauses used to determine the new partitioning scheme are subject to the same rules as those used with a [CREATE TABLE](#) statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by [RANGE](#)) or sets of values (when reorganizing tables partitioned by [LIST](#)).

- The combination of partitions in the [partition_definitions](#) list should account for the same range or set of values overall as the combined partitions named in the [partition_list](#).

For instance, in the [members](#) table used as an example in this section, partitions [p1](#) and [p2](#) together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by [RANGE](#), you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the [members](#) table used as an example in this section using a statement beginning with [ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...](#) because [p0](#) covers the years prior to 1970 and [p2](#) the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use [REORGANIZE PARTITION](#) to change the table's partitioning type; that is, you cannot (for example) change [RANGE](#) partitions to [HASH](#) partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use [ALTER TABLE ... PARTITION BY ...](#). For example:

```
ALTER TABLE members
PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

18.3.2. Management of [HASH](#) and [KEY](#) Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 18.3.1, “Management of \[RANGE\]\(#\) and \[LIST\]\(#\) Partitions”](#).

You cannot drop partitions from tables that are partitioned by [HASH](#) or [KEY](#) in the same way that you can from tables that are partitioned by [RANGE](#) or [LIST](#). However, you can merge [HASH](#) or [KEY](#) partitions using the [ALTER TABLE ... COALESCE PARTITION](#) statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The [clients](#) table is defined as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following [ALTER TABLE](#) command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
->     id INT,
->     fname VARCHAR(30),
->     lname VARCHAR(30),
->     signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

18.3.3. Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.5.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

Beginning with MySQL 5.5.0, you can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

`ALTER TABLE ... TRUNCATE PARTITION ALL` truncates all partitions in the table.

18.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

```

PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
    
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See [Section 13.7.5.37](#), “`SHOW TABLE STATUS Syntax`”, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 20.12](#), “The `INFORMATION_SCHEMA PARTITIONS Table`”.

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```

CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
  PARTITION p2 VALUES LESS THAN (9),
  PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
    
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
        key_len: NULL
         ref: NULL
         rows: 10
      Extra: Using filesort
    
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
    
```

```
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: trb1
      partitions: p0,p1
      type: ALL
      possible_keys: NULL
      key: NULL
      key_len: NULL
      ref: NULL
      rows: 10
      Extra: Using where
```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: trb1
      partitions: p0,p1
      type: range
      possible_keys: PRIMARY
      key: PRIMARY
      key_len: 4
      ref: NULL
      rows: 7
      Extra: Using where
```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN PARTITIONS` output displays the total number of rows in the table.

See also [Section 13.8.2, “EXPLAIN Syntax”](#).

18.4. Partition Pruning

This section discusses an optimization known as *partition pruning*. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
  PARTITION p0 VALUES LESS THAN (64),
  PARTITION p1 VALUES LESS THAN (128),
  PARTITION p2 VALUES LESS THAN (192),
  PARTITION p3 VALUES LESS THAN MAXVALUE
```

```
);
```

Consider the case where you wish to obtain results from a query such as this one:

```
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

Beginning with MySQL 5.5.0, the optimizer can also perform pruning for queries that involve comparisons of the preceding types on multiple columns for tables that use `RANGE COLUMNS` or `LIST COLUMNS` partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` [1152] or `TO_DAYS()` [1148] function. In addition, in MySQL 5.5, pruning can be applied for such tables when the partitioning expression uses the `TO_SECONDS()` [1149] function.

Suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
```

```

PARTITION d2 VALUES LESS THAN (1980),
PARTITION d3 VALUES LESS THAN (1985),
PARTITION d4 VALUES LESS THAN (1990),
PARTITION d5 VALUES LESS THAN (2000),
PARTITION d6 VALUES LESS THAN (2005),
PARTITION d7 VALUES LESS THAN MAXVALUE
);

```

The following queries on `t2` can make use of partition pruning:

```

SELECT * FROM t2 WHERE dob = '1982-06-23';

SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'

```

In the case of the last query, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.

`YEAR('1984-06-21')` [1152] yields the value 1984, which is found in partition `d3`.

2. Find the partition containing the high end of the range.

`YEAR('1999-06-21')` [1152] evaluates to 1999, which is found in partition `d5`.

3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` clause of a query on a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```

CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
);

```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query, such as this one, that compares a column value with a constant can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this query:

```
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by `HASH` or `KEY`. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Note

In MySQL 5.1, a query against a table partitioned by `KEY` and having a composite partitioning key could be pruned only if the query's `WHERE` clause compared every column in the key to a constant. In MySQL 5.5, it is possible to prune queries against such tables even if the `WHERE` clause does not reference every column in the partitioning key.

18.5. Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see [Section 18.5.3, “Partitioning Limitations Relating to Functions”](#).

Arithmetic and logical operators. Use of the arithmetic operators `+` [1121], `-` [1122], and `*` [1122] is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter; see [Section 18.2, “Partitioning Types”](#), for more information).

The `DIV` [1122] operator is also supported, and the `/` [1122] operator is not permitted. (Bug #30188, Bug #33182)

The bit operators `|` [1182], `&` [1182], `^` [1182], `<<` [1183], `>>` [1183], and `~` [1183] are not permitted in partitioning expressions.

Server SQL mode. Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 5.1.7, “Server SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables.*

Examples. The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as `column DIV 0` or `column MOD 0`, as shown here:

```
mysql> CREATE TABLE tn (c1 INT)
->     PARTITION BY LIST(1 DIV c1) (
->         PARTITION p0 VALUES IN (NULL),
->         PARTITION p1 VALUES IN (1)
-> );
Query OK, 0 rows affected (0.05 sec)
```

The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
```

However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
```

```
ERROR 1365 (22012): Division by 0
```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` [614] mode is in effect:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` [614] server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

Performance considerations. Some affects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` [511] is enabled and that `open_files_limit` [535] is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` [528] may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table` [1555].

See also [Maximum number of partitions](#).
- **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.
- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.
- **Use of indexes and partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 18.4, “Partition Pruning”](#), for more information.
- **Performance with `LOAD DATA`.** In MySQL 5.5, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

Maximum number of partitions.

The maximum possible number of partitions for a given table (that does not use the `NDB` storage engine) is 1024. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the `NDBCLUSTER` storage engine is determined according to the version of the MySQL Cluster software being used, the number of data nodes, and other factors. See [NDB and user-defined partitioning](#), for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` [535] system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see [Section C.5.2.18, “'File' Not Found and Similar Errors”](#), for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also [File system operations](#).

Query cache not supported.

The query cache is not supported for partitioned tables. Beginning with MySQL 5.5.23, the query cache is automatically disabled for queries involving partitioned tables, and cannot be enabled for such queries. (Bug #53775)

Per-partition key caches.

In MySQL 5.5, key caches are supported for partitioned `MyISAM` tables, using the `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements. Key caches may be defined for one, several, or all partitions, and indexes for one, several, or all partitions may be preloaded into key caches.

Foreign keys not supported.

Partitioned tables do not support foreign keys. More specifically, this means that the following two statements are true:

1. Definitions of tables employing user-defined partitioning may not contain foreign key references to other tables.
2. No table definition may contain a foreign key reference to a partitioned table.

The scope of these restrictions includes tables that use the [InnoDB](#) storage engine.

ALTER TABLE ... ORDER BY. An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

FULLTEXT indexes.

Partitioned tables do not support [FULLTEXT](#) indexes or searches. This includes partitioned tables employing the [MyISAM](#) storage engine.

Spatial columns. Columns with spatial data types such as [POINT](#) or [GEOMETRY](#) cannot be used in partitioned tables.

Temporary tables.

Temporary tables cannot be partitioned. (Bug #17497)

Log tables. It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

Data type of partitioning key.

A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be [NULL](#). (See [Section 18.2.7, “How MySQL Partitioning Handles NULL”](#).)

There are two exceptions to this restriction:

1. When partitioning by [\[LINEAR\] KEY](#), it is possible to use columns of other types as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

2. When partitioning by [RANGE COLUMNS](#) or [LIST COLUMNS](#), it is possible to use string, [DATE](#), and [DATETIME](#) columns. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc (c1 INT, c2 DATE)
PARTITION BY RANGE COLUMNS(c2) (
  PARTITION p0 VALUES LESS THAN('1990-01-01'),
  PARTITION p1 VALUES LESS THAN('1995-01-01'),
  PARTITION p2 VALUES LESS THAN('2000-01-01'),
  PARTITION p3 VALUES LESS THAN('2005-01-01'),
  PARTITION p4 VALUES LESS THAN(MAXVALUE)
);

CREATE TABLE lc (c1 INT, c2 CHAR(1))
PARTITION BY LIST COLUMNS(c2) (
  PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
  PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
  PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
);
```

Neither of the preceding exceptions applies to [BLOB](#) or [TEXT](#) column types.

Subqueries.

A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.

Issues with subpartitions.

Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

Currently, `SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY()
-> SUBPARTITIONS 4
-> (
->   PARTITION p0 VALUES LESS THAN (100),
->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ')'

mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY(id)
-> SUBPARTITIONS 4
-> (
```

```

-> PARTITION p0 VALUES LESS THAN (100),
-> PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.07 sec)

```

This is a known issue (see Bug #51470).

DELAYED option not supported. Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Attempting to do so fails with an error.

DATA DIRECTORY and INDEX DIRECTORY options. `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:

- Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091).
- On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions (Bug #30459).

Repairing and rebuilding partitioned tables. The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See [Section 13.1.7, “ALTER TABLE Syntax”](#), for more information about these two statements.

`mysqlcheck` and `myisamchk` are not supported with partitioned tables.

18.5.1. Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression.* (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```

CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;

```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2, col3),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
  col1 INT NOT NULL,
  col2 INT NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col3),
```

```

        UNIQUE KEY (col2, col4)
    );

```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```

CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),
    UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;

```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```

CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```

mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
->     PARTITION BY RANGE(c1) (
->         PARTITION p0 VALUES LESS THAN (10),
->         PARTITION p1 VALUES LESS THAN (20),
->         PARTITION p2 VALUES LESS THAN (30),
->         PARTITION p3 VALUES LESS THAN (40)
->     );

```

```
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (
->   id INT NOT NULL AUTO_INCREMENT,
->   name VARCHAR(50),
->   added DATE,
->   PRIMARY KEY (id)
-> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH( TO_DAYS(added) )
->   PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH(id)
->   PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first

modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

18.5.2. Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

MERGE storage engine. User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

FEDERATED storage engine. Partitioning of `FEDERATED` tables is not supported; it is not possible to create partitioned `FEDERATED` tables.

CSV storage engine. Partitioned tables using the `CSV` storage engine are not supported; it is not possible to create partitioned `CSV` tables.

InnoDB storage engine. `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the `InnoDB` storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead. For more information, see [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

NDBCLUSTER storage engine (MySQL Cluster). Partitioning by `KEY` (including `LINEAR KEY`) is the only type of partitioning supported for the `NDBCLUSTER` storage engine. It is not possible in MySQL Cluster NDB 7.2 to create a MySQL Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so fails with an error.

In addition, the maximum number of partitions that can be defined for an `NDBCLUSTER` table depends on the number of data nodes and node groups in the cluster, the version of the MySQL Cluster software in use, and other factors. See [NDB and user-defined partitioning](#), for more information.

`CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned `NDBCLUSTER` table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned `NDBCLUSTER` table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than `NDBCLUSTER` must be dumped and reloaded.

Same storage engine for all partitions. All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

18.5.3. Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following table are supported in partitioning expressions.

| | | |
|---|---|---|
| ABS() [1123] | CEILING() [1125] (see CEILING() and FLOOR()) | DAY() [1139] |
| DAYOFMONTH() [1140] | DAYOFWEEK() [1140] | DAYOFYEAR() [1140] |
| DATEDIFF() [1135] | EXTRACT() [1140] (see EXTRACT() function with WEEK specifier) | FLOOR() [1126] (see CEILING() and FLOOR()) |
| HOUR() [1142] | MICROSECOND() [1142] | MINUTE() [1142] |
| MOD() [1127] | MONTH() [1143] | QUARTER() [1144] |
| SECOND() [1144] | TIME_TO_SEC() [1148] | TO_DAYS() [1148] |
| TO_SECONDS() [1149] (implemented in MySQL 5.5.0) | UNIX_TIMESTAMP() [1150] (permitted beginning with MySQL 5.5.1 and fully supported beginning with MySQL 5.5.15, with TIMESTAMP columns) | WEEKDAY() [1152] |
| YEAR() [1152] | | YEARWEEK() [1152] |

In MySQL 5.5, partition pruning is supported for the [TO_DAYS\(\) \[1148\]](#), [TO_SECONDS\(\) \[1149\]](#), and [YEAR\(\) \[1152\]](#) functions. In addition, beginning with MySQL 5.5.15, [UNIX_TIMESTAMP\(\) \[1150\]](#) is treated as monotonic in partitioning expressions. See [Section 18.4, “Partition Pruning”](#), for more information.

CEILING() and FLOOR(). Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the [INT](#) types or [DECIMAL](#). This means, for example, that the following [CREATE TABLE](#) statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
->     PARTITION p0 VALUES IN (1,3,5),
->     PARTITION p1 VALUES IN (2,4,6)
-> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

EXTRACT() function with WEEK specifier. The value returned by the [EXTRACT\(\) \[1140\]](#) function, when used as [EXTRACT\(WEEK FROM col\) \[1140\]](#), depends on the value of the [default_week_format \[494\]](#) system variable. For this reason, beginning with MySQL 5.5.9, [EXTRACT\(\) \[1140\]](#) is longer permitted as a partitioning function when it specifies the unit as [WEEK](#). (Bug #54483)

See [Section 12.6.2, “Mathematical Functions”](#), for more information about the return types of these functions, as well as [Section 11.2, “Numeric Types”](#).

18.5.4. Partitioning and Table-Level Locking

For storage engines such as [MyISAM](#) that actually execute table-level locks when executing DML or DDL statements, such a statement affecting a partitioned table imposes a lock on the table as a whole; that is, all partitions are locked until the statement was finished. For example, a [SELECT](#) from a partitioned [MyISAM](#) table causes a lock on the entire table.

In practical terms, what this means is that the statements discussed later in this section tend to execute more slowly as the number of partitions increases. This limitation is greatly reduced in MySQL 5.6, with the introduction of *partition lock pruning* in MySQL 5.6.6.

This is not true for statements effecting partitioned tables using storage engines such as [InnoDB](#), that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning.

The next few paragraphs discuss the effects of MySQL statements on partitioned tables using storage engines that employ table-level locks.

DML statements

`SELECT` statements lock the entire table. `SELECT` statements containing unions or joins lock all tables named in the union or join.

`UPDATE` also locks the entire table.

`REPLACE` and `INSERT` (including `INSERT ... ON DUPLICATE KEY UPDATE`) lock the entire table.

`INSERT ... SELECT` locks both the source table and the target table.

Note

`INSERT DELAYED` is not supported for partitioned tables.

A `LOAD DATA` statement on a partitioned table locks the entire table.

A trigger on a partitioned table, once activated, locks the entire table.

DDL statements

`CREATE VIEW` causes a lock on any partitioned table from which it reads.

`ALTER TABLE` locks the affected partitioned table.

Other statements

`LOCK TABLES` locks all partitions of a partitioned table.

Evaluating the `expr` in a `CALL stored_procedure(expr)` statement locks all partitions of any partitioned table referenced by `expr`.

`ALTER TABLE` also takes a metadata lock on the table level.

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See [Section 13.1, “Data Definition Statements”](#).

- The `CALL` statement is used to invoke stored procedures. See [Section 13.2.1, “CALL Syntax”](#).
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See [Section 13.6, “MySQL Compound-Statement Syntax”](#).

19.1. Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (“`\`”) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
```

```
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

19.2. Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.5. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.5 installation procedure. If you are upgrading to MySQL 5.5 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section B.4, “MySQL 5.5 FAQ: Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section E.1, “Restrictions on Stored Programs”](#).
- Binary logging for stored routines takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

19.2.1. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see [Section 13.1.15](#), “`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax”). A procedure is invoked using a `CALL` statement (see [Section 13.2.1](#), “`CALL` Syntax”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 13.6](#), “`MySQL Compound-Statement Syntax`”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see [Section 13.1.26](#), “`DROP PROCEDURE` and `DROP FUNCTION` Syntax”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see [Section 13.1.5](#), “`ALTER PROCEDURE` Syntax”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` [525] server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth` [525], it may be necessary to increase thread stack size by increasing the value of `thread_stack` [566] at server startup. See [Section 5.1.4](#), “`Server System Variables`”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [Section 22.8.3.52](#), “`mysql_real_connect()`”, and [Section 22.8.13](#), “`C API Support for Multiple Statement Execution`”.

19.2.2. Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` [695] privilege is needed to create stored routines.
- The `ALTER ROUTINE` [695] privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` [696] privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is

dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` [484] system variable is 0, the `EXECUTE` [696] and `ALTER ROUTINE` [695] privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

19.2.3. Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 20.17, “The INFORMATION_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 13.7.5.29, “SHOW PROCEDURE STATUS Syntax”](#).

19.2.4. Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` [1194] changes the same way as for statements executed outside the body of these kinds of objects (see [Section 12.14, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` [1194] that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()` [1194], the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

19.3. Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement executes for the associated table. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in views, nor by changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that:

- Triggers are not activated by changes in `INFORMATION_SCHEMA` tables, because these tables are actually views.
- Triggers are not activated by updates made using the `NDB` API.

To use triggers if you have upgraded to MySQL 5.5 from an older release that did not support triggers, you should upgrade your grant tables so that they contain the trigger-related privileges. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

The following discussion describes the syntax for creating and dropping triggers, and shows some examples of how to use them.

Additional Resources

- You may find the [Triggers User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding triggers in MySQL, see [Section B.5, “MySQL 5.5 FAQ: Triggers”](#).
- There are some restrictions on the use of triggers; see [Section E.1, “Restrictions on Stored Programs”](#).
- Binary logging for triggers takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

19.3.1. Trigger Syntax

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in [Section 13.1.19, “CREATE TRIGGER Syntax”](#), and [Section 13.1.30, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table for `INSERT` statements. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other permissible keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Triggers for a table are also dropped if you drop the table.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` [697] privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` [697] privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
```

```
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple [CALL](#) statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the [CALL](#) statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through [OUT](#) or [INOUT](#) parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as [START TRANSACTION](#), [COMMIT](#), or [ROLLBACK](#).

MySQL handles errors during trigger execution as follows:

- If a [BEFORE](#) trigger fails, the operation on the corresponding row is not performed.
- A [BEFORE](#) trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An [AFTER](#) trigger is executed only if the [BEFORE](#) trigger (if any) and the row operation both execute successfully.
- An error during either a [BEFORE](#) or [AFTER](#) trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

19.3.2. Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the [TRIGGERS](#) table of the [INFORMATION_SCHEMA](#) database. See [Section 20.25](#), “[The INFORMATION_SCHEMA TRIGGERS Table](#)”.
- Use the [SHOW TRIGGERS](#) statement. See [Section 13.7.5.39](#), “[SHOW TRIGGERS Syntax](#)”.

19.4. Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events: Tasks that run according to schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 19.4.1](#), “[Event Scheduler Overview](#)”, provides an introduction to and conceptual overview of MySQL Events.

- [Section 19.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 19.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.5 installation procedure. If you are upgrading to MySQL 5.5 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

Additional Resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section E.1, “Restrictions on Stored Programs”](#).
- Binary logging for events takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

19.4.1. Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in [Section 19.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.5, an event is uniquely identified by its name and the schema to which it is assigned.
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 13.6, “MySQL Compound-Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent

simultaneous instances. For example, you could use the `GET_LOCK()` [1199] function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 13.1.2, “ALTER EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` [696] privilege on the database for which the event is defined. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section E.1, “Restrictions on Stored Programs”](#).

19.4.2. Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` [696] privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` [498] system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- **OFF:** The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler` [498].

When the Event Scheduler is stopped (`event_scheduler` [498] is **OFF**), it can be started by setting the value of `event_scheduler` [498] to **ON**. (See next item.)

- **ON:** The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 1
  User: root
  Host: localhost
  db: NULL
Command: Query
  Time: 0
  State: NULL
  Info: show processlist
***** 2. row *****
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
```

```
Command: Daemon
Time: 3
State: Waiting for next activation
Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` [498] to `OFF`.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` [498] can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` [498] by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. **DISABLED** has no numeric equivalent. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` [498] without specifying it as a global variable causes an error:

```
mysql> SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL
```

Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` [498] is **ON** or **OFF**, you cannot set it to **DISABLED** at runtime. Also, if the Event Scheduler is set to **DISABLED** at startup, you cannot change the value of `event_scheduler` [498] at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` [443] command-line option, or after removing or commenting out the line containing `event-`

`scheduler=DISABLED` [443] in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` [498] is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` [461] option causes `event_scheduler` [498] to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see [Section 19.4.3, “Event Syntax”](#).

MySQL 5.5 provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 19.4.4, “Event Metadata”](#), and [Section 20.7, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

19.4.3. Event Syntax

MySQL 5.5 provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 13.1.11, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 13.1.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 13.1.22, “DROP EVENT Syntax”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 13.1.11, “CREATE EVENT Syntax”](#).

An event can be dropped by any user having the `EVENT` [696] privilege for the database on which the event is defined. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

19.4.4. Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 20.7, “The INFORMATION_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 13.7.5.9, “SHOW CREATE EVENT Syntax”](#).
- Use the `SHOW EVENTS` statement. See [Section 13.7.5.19, “SHOW EVENTS Syntax”](#).

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` [567] value that is initialized from the server's global `time_zone` [567] value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

| Value | <code>mysql.event</code> | <code>INFORMATION_SCHEMA.EVENTS</code> | <code>SHOW EVENTS</code> |
|---------------|--------------------------|--|--------------------------|
| Execute at | UTC | ETZ | ETZ |
| Starts | UTC | ETZ | ETZ |
| Ends | UTC | ETZ | ETZ |
| Last executed | UTC | ETZ | n/a |
| Created | STZ | STZ | n/a |
| Last altered | STZ | STZ | n/a |

19.4.5. Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example.

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained by running `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA       : init_scheduler:313
LUA       : init_scheduler:318
WOC       : NO
Workers   : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count : 1
```

```
Data locked      : NO
Attempting lock : NO
LLA             : init_queue:148
LUA             : init_queue:168
WOC             : NO
Next activation  : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

19.4.6. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` [\[498\]](#) system variable. This requires the `SUPER` [\[697\]](#) privilege.

The `EVENT` [\[696\]](#) privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` [\[696\]](#) privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` [\[696\]](#) privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` [\[696\]](#) privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` [\[696\]](#) privilege for `myschema`. Suppose also that this user has the `SELECT` [\[697\]](#) privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
  EVERY 10 SECOND
DO
  INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` [\[696\]](#) privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:39:54 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:40:04 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT [696]` privilege, use the `REVOKE` statement. In this example, the `EVENT [696]` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

Important

Revoking the `EVENT [696]` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT [696]` and `INSERT [696]` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
```

```
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT [696]` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 20.7, “The INFORMATION_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
WHERE db = 'myschema'
  AND definer = 'jon@ghidora'
  AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Users' `EVENT [696]` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT [696]` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT [696]` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see [Section E.1, “Restrictions on Stored Programs”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

19.5. Using Views

Views (including updatable views) are available in MySQL Server 5.5. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.5 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section B.6, “MySQL 5.5 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section E.5, “Restrictions on Views”](#).

19.5.1. View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 13.1.20, “CREATE VIEW Syntax”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 13.1.9, “ALTER VIEW Syntax”](#)), or `DROP VIEW` (see [Section 13.1.31, “DROP VIEW Syntax”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty  | price | value |
+-----+-----+-----+
| 3    | 50    | 150   |
| 5    | 60    | 300   |
+-----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+-----+-----+-----+
| qty  | price | value |
+-----+-----+-----+
| 5    | 60    | 300   |
+-----+-----+-----+
```

19.5.2. View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` [1094] connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()` [1206], `MIN()` [1206], `MAX()` [1205], `COUNT()` [1204], and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`

- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

19.5.3. Updatable and Insertable Views

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()` [1206], `MIN()` [1206], `MAX()` [1205], `COUNT()` [1204], and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Nonupdatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- Uses `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are not permitted even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()` [1194], because the side effects of inserting default values into columns not part of the view should not be visible.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` [571] system variable. See [Section 5.1.4, “Server System Variables”](#).

19.5.4. View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 20.27, “The INFORMATION_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 13.7.5.14, “SHOW CREATE VIEW Syntax”](#).

19.6. Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute, and, if there is one, their `SQL SECURITY` characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a `DEFINER` attribute that names a MySQL account. If the `DEFINER` attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the `SQL SECURITY` characteristic is omitted, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` [696] to call a stored procedure or `SELECT` [697] to select from a view), but when the object executes, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a `root` account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` [696] privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in `DEFINER` security context and thus executes with the privileges of `'admin'@'localhost'`, the account named in the `DEFINER` attribute. This account must have the `EXECUTE` [696] privilege for `p1` as well as the `UPDATE` [697] privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

`p2`, unlike `p1`, executes in `INVOKER` security context. The `DEFINER` attribute is irrelevant and `p2` executes with the privileges of the invoking user. `p2` fails if the invoker lacks the `EXECUTE` [696] privilege for `p2` or the `UPDATE` [697] privilege for the table `t1`.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- You can specify a `DEFINER` value other than your own account only if you have the `SUPER` [697] privilege.
- If you do not have the `SUPER` [697] privilege, the only legal user value is your own account, either specified literally or by using `CURRENT_USER` [1192]. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the `SUPER` [697] privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged `DEFINER` accounts by not granting them the `SUPER` [697] privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
 - A stored procedure or function cannot be referenced by a user who does not have the `EXECUTE` [696] privilege for it.
 - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` [697] to select from it, `INSERT` [696] to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in `DEFINER` context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the `DEFINER` account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the `SUPER` [697] and `TRIGGER` [697] privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

19.7. Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 16.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.3.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.5 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see [Section 16.1.2, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin [1892]` option. (See [Section 5.2.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.5 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER [697]` privilege, in addition to the `CREATE ROUTINE [695]` or `ALTER ROUTINE [695]` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER [697]` might be required regardless of whether binary logging is enabled. See [Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
```

(you *might* want to use the less safe `log_bin_trust_function_creators` variable)

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()` [1201], which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.
- To relax the preceding conditions on function creation (that you must have the `SUPER` [697] privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` [514] system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` [1892] option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` [514] does not apply. `SUPER` [697] is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 16.4.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` [1201] function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
 - It is possible for a function to follow different execution paths on master and slave servers.
 - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` [695] privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->   IF @@server_id=2 THEN dangerous_statement; END IF;
->   RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` [697] privilege, in addition to the usual `CREATE ROUTINE` [695] privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` [697] privilege in addition to the `ALTER ROUTINE` [695] privilege. Without the `SUPER` [697] privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` [697] privilege (for example, if all users with the `CREATE ROUTINE` [695] privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` [514] system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` [1892] option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` [514] does not apply. `SUPER` [697] is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
 - It will make a slave different from the master.
 - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
```

```
variable)
```

If you set `log_bin_trust_function_creators` [514] to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` [1201] has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` [1201] enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` [1201] can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` [1201] expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with

the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
 - Updates to transactional tables are not logged.
 - Updates to nontransactional tables are logged because rollback does not cancel them.
 - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 20. INFORMATION_SCHEMA Tables

`INFORMATION_SCHEMA` provides access to database *metadata*, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are *data dictionary* and *system catalog*.

Usage Notes for the `INFORMATION_SCHEMA` Database

`INFORMATION_SCHEMA` is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The `INFORMATION_SCHEMA` database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select `INFORMATION_SCHEMA` as the default database with a `USE` statement, you can only read the contents of tables, not perform `INSERT`, `UPDATE`, or `DELETE` operations on them.

Example

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name;
```

| table_name | table_type | engine |
|------------|------------|--------|
| fk | BASE TABLE | InnoDB |
| fk2 | BASE TABLE | InnoDB |
| goto | BASE TABLE | MyISAM |
| into | BASE TABLE | MyISAM |
| k | BASE TABLE | MyISAM |
| kurs | BASE TABLE | MyISAM |
| loop | BASE TABLE | MyISAM |
| pk | BASE TABLE | InnoDB |
| t | BASE TABLE | MyISAM |
| t2 | BASE TABLE | MyISAM |
| t3 | BASE TABLE | MyISAM |
| t7 | BASE TABLE | MyISAM |
| tables | BASE TABLE | MyISAM |
| v | VIEW | NULL |
| v2 | VIEW | NULL |
| v3 | VIEW | NULL |
| v56 | VIEW | NULL |

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns. However, searches in `INFORMATION_SCHEMA` string columns are also affected by file system case sensitivity. For more information, see [Section 10.1.7.9, "Collation and `INFORMATION_SCHEMA` Searches"](#).

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges will see `NULL`.

Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see [Section 10.1.7.9, “Collation and `INFORMATION_SCHEMA` Searches”](#).

`INFORMATION_SCHEMA` as Alternative to `SHOW` Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in [Section 20.31, “Extensions to `SHOW` Statements”](#).

Privileges

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges see `NULL`. These restrictions do not apply for `InnoDB` tables; you can see them with only the `PROCESS [696]` privilege.

The same privileges apply to selecting information from `INFORMATION_SCHEMA` and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

Performance Considerations

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune `INFORMATION_SCHEMA` queries, see [Section 8.2.4, “Optimizing `INFORMATION_SCHEMA` Queries”](#).

Standards Considerations

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: http://web.archive.org/web/20070409075643rn_1/www.dbazine.com/db2/db2-disarticles/gulutzan5.

Conventions in the `INFORMATION_SCHEMA` Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

For information about `INFORMATION_SCHEMA` tables specific to the `InnoDB` storage engine, see [Section 20.28, “`INFORMATION_SCHEMA` Tables for `InnoDB`”](#). For information about `INFORMATION_SCHEMA` tables specific to the `NDB` storage engine (MySQL Cluster), see [Section 20.29, “`INFORMATION_SCHEMA` Tables for MySQL Cluster”](#). For information about `INFORMATION_SCHEMA` tables specific to the thread pool plugin, see [Section 20.30, “`Thread Pool` `INFORMATION_SCHEMA` Tables”](#).

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see [Section B.7, “`MySQL 5.5 FAQ: INFORMATION_SCHEMA`”](#).

20.1. The `INFORMATION_SCHEMA.CHARACTER_SETS` Table

The `CHARACTER_SETS` table provides information about available character sets.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|--------------------------------|-----------------|
| <code>CHARACTER_SET_NAME</code> | <code>Charset</code> | |
| <code>DEFAULT_COLLATE_NAME</code> | <code>Default collation</code> | |
| <code>DESCRIPTION</code> | <code>Description</code> | MySQL extension |
| <code>MAXLEN</code> | <code>Maxlen</code> | MySQL extension |

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

20.2. The `INFORMATION_SCHEMA` `COLLATIONS` Table

The `COLLATIONS` table provides information about collations for each character set.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|-----------------|
| <code>COLLATION_NAME</code> | Collation | |
| <code>CHARACTER_SET_NAME</code> | Charset | MySQL extension |
| <code>ID</code> | Id | MySQL extension |
| <code>IS_DEFAULT</code> | Default | MySQL extension |
| <code>IS_COMPILED</code> | Compiled | MySQL extension |
| <code>SORTLEN</code> | Sortlen | MySQL extension |

- `COLLATION_NAME` is the collation name.
- `CHARACTER_SET_NAME` is the name of the character set with which the collation is associated.
- `ID` is the collation ID.
- `IS_DEFAULT` indicates whether the collation is the default for its character set.
- `IS_COMPILED` indicates whether the character set is compiled into the server.
- `SORTLEN` is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the `SHOW COLLATION` statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

20.3. The `INFORMATION_SCHEMA` `COLLATION_CHARACTER_SET_APPLICABILITY` Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---------|
| <code>COLLATION_NAME</code> | Collation | |
| <code>CHARACTER_SET_NAME</code> | Charset | |

20.4. The `INFORMATION_SCHEMA` `COLUMNS` Table

The `COLUMNS` table provides information about columns in tables.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|--------------------------|------------|-----------------|
| TABLE_CATALOG | | def |
| TABLE_SCHEMA | | |
| TABLE_NAME | | |
| COLUMN_NAME | Field | |
| ORDINAL_POSITION | | see notes |
| COLUMN_DEFAULT | Default | |
| IS_NULLABLE | Null | |
| DATA_TYPE | Type | |
| CHARACTER_MAXIMUM_LENGTH | Type | |
| CHARACTER_OCTET_LENGTH | | |
| NUMERIC_PRECISION | Type | |
| NUMERIC_SCALE | Type | |
| CHARACTER_SET_NAME | | |
| COLLATION_NAME | Collation | |
| COLUMN_TYPE | Type | MySQL extension |
| COLUMN_KEY | Key | MySQL extension |
| EXTRA | Extra | MySQL extension |
| PRIVILEGES | Privileges | MySQL extension |
| COLUMN_COMMENT | Comment | MySQL extension |

Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

20.5. The `INFORMATION_SCHEMA.COLUMN_PRIVILEGES` Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---|
| <code>GRANTEE</code> | | ' <code>user_name</code> '@' <code>host_name</code> ' value |
| <code>TABLE_CATALOG</code> | | <code>def</code> |
| <code>TABLE_SCHEMA</code> | | |
| <code>TABLE_NAME</code> | | |
| <code>COLUMN_NAME</code> | | |
| <code>PRIVILEGE_TYPE</code> | | |
| <code>IS_GRANTABLE</code> | | |

Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT` [697], `INSERT` [696], `UPDATE` [697], `REFERENCES` [696].
- If the user has `GRANT OPTION` [696] privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` [696] as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

20.6. The `INFORMATION_SCHEMA.ENGINES` Table

The `PLUGINS` table provides information about storage engines.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|---------------------------|-----------------|
| <code>ENGINE</code> | <code>Engine</code> | MySQL extension |
| <code>SUPPORT</code> | <code>Support</code> | MySQL extension |
| <code>COMMENT</code> | <code>Comment</code> | MySQL extension |
| <code>TRANSACTIONS</code> | <code>Transactions</code> | MySQL extension |
| <code>XA</code> | <code>XA</code> | MySQL extension |
| <code>SAVEPOINTS</code> | <code>Savepoints</code> | MySQL extension |

Notes:

- The `ENGINES` table is a nonstandard table.

See also [Section 13.7.5.17](#), “SHOW ENGINES Syntax”.

20.7. The INFORMATION_SCHEMA EVENTS Table

The `EVENTS` table provides information about scheduled events, which are discussed in [Section 19.4](#), “Using the Event Scheduler”. The `SHOW Name` values correspond to column names of the `SHOW EVENTS` statement.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|--|----------------------|
| EVENT_CATALOG | | def, MySQL extension |
| EVENT_SCHEMA | Db | MySQL extension |
| EVENT_NAME | Name | MySQL extension |
| DEFINER | Definer | MySQL extension |
| TIME_ZONE | Time zone | MySQL extension |
| EVENT_BODY | | MySQL extension |
| EVENT_DEFINITION | | MySQL extension |
| EVENT_TYPE | Type | MySQL extension |
| EXECUTE_AT | Execute at | MySQL extension |
| INTERVAL_VALUE | Interval value | MySQL extension |
| INTERVAL_FIELD | Interval field | MySQL extension |
| SQL_MODE | | MySQL extension |
| STARTS | Starts | MySQL extension |
| ENDS | Ends | MySQL extension |
| STATUS | Status | MySQL extension |
| ON_COMPLETION | | MySQL extension |
| CREATED | | MySQL extension |
| LAST_ALTERED | | MySQL extension |
| LAST_EXECUTED | | MySQL extension |
| EVENT_COMMENT | | MySQL extension |
| ORIGINATOR | Originator | MySQL extension |
| CHARACTER_SET_CLIENT | character_set_client | MySQL extension |
| COLLATION_CONNECTION | collation_connection [489] | MySQL extension |
| DATABASE_COLLATION | Database Collation | MySQL extension |

Notes:

- The `EVENTS` table is a nonstandard table.
- `EVENT_CATALOG`: The value of this column is always `def`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in '`user_name`'@'`host_name`' format.

- **TIME_ZONE**: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is **SYSTEM**.
- **EVENT_BODY**: The language used for the statements in the event's **DO** clause; in MySQL 5.5, this is always **SQL**.

This column is not to be confused with the column of the same name (now named **EVENT_DEFINITION**) that existed in earlier MySQL versions.

- **EVENT_DEFINITION**: The text of the SQL statement making up the event's **DO** clause; in other words, the statement executed by this event.
- **EVENT_TYPE**: The event repetition type, either **ONE TIME** (transient) or **RECURRING** (repeating).
- **EXECUTE_AT**: For a one-time event, this is the **DATETIME** value specified in the **AT** clause of the **CREATE EVENT** statement used to create the event, or of the last **ALTER EVENT** statement that modified the event. The value shown in this column reflects the addition or subtraction of any **INTERVAL** value included in the event's **AT** clause. For example, if an event is created using **ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR**, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be `'2006-02-10 20:05:30'`.

If the event's timing is determined by an **EVERY** clause instead of an **AT** clause (that is, if the event is recurring), the value of this column is **NULL**.

- **INTERVAL_VALUE**: For recurring events, this column contains the numeric portion of the event's **EVERY** clause.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column is **NULL**.

- **INTERVAL_FIELD**: For recurring events, this column contains the units portion of the **EVERY** clause governing the timing of the event. Thus, this column contains a value such as **'YEAR'**, **'QUARTER'**, **'DAY'**, and so on.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column is **NULL**.

- **SQL_MODE**: The SQL mode in effect at the time the event was created or altered.
- **STARTS**: For a recurring event whose definition includes a **STARTS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE_AT** column, this value resolves any expressions used.

If there is no **STARTS** clause affecting the timing of the event, this column is **NULL**.

- **ENDS**: For a recurring event whose definition includes a **ENDS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE_AT** column, this value resolves any expressions used.

If there is no **ENDS** clause affecting the timing of the event, this column is **NULL**.

- **STATUS**: One of the three values **ENABLED**, **DISABLED**, or **SLAVESIDE_DISABLED**.

SLAVESIDE_DISABLED indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 16.4.1.10, "Replication of Invoked Features"](#), for more information.

- **ON_COMPLETION**: One of the two values `PRESERVE` or `NOT PRESERVE`.
- **CREATED**: The date and time when the event was created. This is a `DATETIME` value.
- **LAST_ALTERED**: The date and time when the event was last modified. This is a `DATETIME` value. If the event has not been modified since its creation, this column holds the same value as the `CREATED` column.
- **LAST_EXECUTED**: The date and time when the event last executed. A `DATETIME` value. If the event has never executed, this column is `NULL`.

`LAST_EXECUTED` indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

- **EVENT_COMMENT**: The text of a comment, if the event has one. If not, the value of this column is an empty string.
- **ORIGINATOR**: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0.
- **CHARACTER_SET_CLIENT** is the session value of the `character_set_client` [486] system variable when the event was created. **COLLATION_CONNECTION** is the session value of the `collation_connection` [489] system variable when the event was created. **DATABASE_COLLATION** is the collation of the database with which the event is associated.

Example: Suppose that the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
INSERT INTO site_activity.totals (time, total)
SELECT CURRENT_TIMESTAMP, COUNT(*)
FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END |
DELIMITER ;
ALTER EVENT e_daily
ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: def
EVENT_SCHEMA: test
EVENT_NAME: e_daily
DEFINER: paul@localhost
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
```

```

INSERT INTO site_activity.totals (time, total)
  SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE:
  STARTS: 2008-09-03 12:13:39
  ENDS: NULL
  STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
  CREATED: 2008-09-03 12:13:39
  LAST_ALTERED: 2008-09-03 12:13:39
  LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions then clears the
                table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
DATABASE_COLLATION: latin1_swedish_ci

```

Times in the `EVENTS` table are displayed using the event time zone or the current session time zone, as described in [Section 19.4.4, “Event Metadata”](#).

See also [Section 13.7.5.19, “SHOW EVENTS Syntax”](#).

20.8. The `INFORMATION_SCHEMA GLOBAL_STATUS` and `SESSION_STATUS` Tables

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 13.7.5.36, “SHOW STATUS Syntax”](#)).

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---------|
| <code>VARIABLE_NAME</code> | Variable_name | |
| <code>VARIABLE_VALUE</code> | Value | |

Notes:

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`.

20.9. The `INFORMATION_SCHEMA GLOBAL_VARIABLES` and `SESSION_VARIABLES` Tables

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 13.7.5.40, “SHOW VARIABLES Syntax”](#)).

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---------|
| <code>VARIABLE_NAME</code> | Variable_name | |
| <code>VARIABLE_VALUE</code> | Value | |

Notes:

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`.

20.10. The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|--|-----------|---------|
| <code>CONSTRAINT_CATALOG</code> | | def |
| <code>CONSTRAINT_SCHEMA</code> | | |
| <code>CONSTRAINT_NAME</code> | | |
| <code>TABLE_CATALOG</code> | | def |
| <code>TABLE_SCHEMA</code> | | |
| <code>TABLE_NAME</code> | | |
| <code>COLUMN_NAME</code> | | |
| <code>ORDINAL_POSITION</code> | | |
| <code>POSITION_IN_UNIQUE_CONSTRAINT</code> | | |
| <code>REFERENCED_TABLE_SCHEMA</code> | | |
| <code>REFERENCED_TABLE_NAME</code> | | |
| <code>REFERENCED_COLUMN_NAME</code> | | |

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.

- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.

20.11. The INFORMATION_SCHEMA PARAMETERS Table

The `PARAMETERS` table provides information about stored procedure and function parameters, and about return values for stored functions. Parameter information is similar to the contents of the `param_list` column in the `mysql.proc` table.

| INFORMATION_SCHEMA Name | mysql.proc Name | Remarks |
|---------------------------------------|-------------------|--|
| <code>SPECIFIC_CATALOG</code> | | <code>def</code> |
| <code>SPECIFIC_SCHEMA</code> | <code>db</code> | routine database |
| <code>SPECIFIC_NAME</code> | <code>name</code> | routine name |
| <code>ORDINAL_POSITION</code> | | 1, 2, 3, ... for parameters, 0 for function <code>RETURNS</code> clause |
| <code>PARAMETER_MODE</code> | | <code>IN</code> , <code>OUT</code> , <code>INOUT</code> (<code>NULL</code> for <code>RETURNS</code>) |
| <code>PARAMETER_NAME</code> | | parameter name (<code>NULL</code> for <code>RETURNS</code>) |
| <code>DATA_TYPE</code> | | same as for <code>COLUMNS</code> table |
| <code>CHARACTER_MAXIMUM_LENGTH</code> | | same as for <code>COLUMNS</code> table |
| <code>CHARACTER_OCTET_LENGTH</code> | | same as for <code>COLUMNS</code> table |
| <code>NUMERIC_PRECISION</code> | | same as for <code>COLUMNS</code> table |
| <code>NUMERIC_SCALE</code> | | same as for <code>COLUMNS</code> table |
| <code>CHARACTER_SET_NAME</code> | | same as for <code>COLUMNS</code> table |
| <code>COLLATION_NAME</code> | | same as for <code>COLUMNS</code> table |
| <code>DTD_IDENTIFIER</code> | | same as for <code>COLUMNS</code> table |
| <code>ROUTINE_TYPE</code> | <code>type</code> | same as for <code>ROUTINES</code> table |

Notes:

- The `PARAMETERS` table was added in MySQL 5.5.3.
- For successive parameters of a stored procedure or function, the `ORDINAL_POSITION` values are 1, 2, 3, and so forth. For a stored function, there is also a row that describes the data type for the `RETURNS` clause. The return value is not a true parameter, so the row that describes it has these unique characteristics:
 - The `ORDINAL_POSITION` value is 0.
 - The `PARAMETER_NAME` and `PARAMETER_MODE` values are `NULL` because the return value has no name and the mode does not apply.

20.12. The INFORMATION_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 18, Partitioning](#), for more information about partitioning tables.

The INFORMATION_SCHEMA PARTITIONS Table

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------------|-----------|-----------------|
| TABLE_CATALOG | | MySQL extension |
| TABLE_SCHEMA | | MySQL extension |
| TABLE_NAME | | MySQL extension |
| PARTITION_NAME | | MySQL extension |
| SUBPARTITION_NAME | | MySQL extension |
| PARTITION_ORDINAL_POSITION | | MySQL extension |
| SUBPARTITION_ORDINAL_POSITION | | MySQL extension |
| PARTITION_METHOD | | MySQL extension |
| SUBPARTITION_METHOD | | MySQL extension |
| PARTITION_EXPRESSION | | MySQL extension |
| SUBPARTITION_EXPRESSION | | MySQL extension |
| PARTITION_DESCRIPTION | | MySQL extension |
| TABLE_ROWS | | MySQL extension |
| AVG_ROW_LENGTH | | MySQL extension |
| DATA_LENGTH | | MySQL extension |
| MAX_DATA_LENGTH | | MySQL extension |
| INDEX_LENGTH | | MySQL extension |
| DATA_FREE | | MySQL extension |
| CREATE_TIME | | MySQL extension |
| UPDATE_TIME | | MySQL extension |
| CHECK_TIME | | MySQL extension |
| CHECKSUM | | MySQL extension |
| PARTITION_COMMENT | | MySQL extension |
| NODEGROUP | | MySQL extension |
| TABLESPACE_NAME | | MySQL extension |

Notes:

- The `PARTITIONS` table is a nonstandard table.
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `def`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added,

dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.

- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- `PARTITION_METHOD`: One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 18.2, “Partitioning Types”](#).
- `SUBPARTITION_METHOD`: One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 18.2.6, “Subpartitioning”](#).
- `PARTITION_EXPRESSION`: This is the expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table’s current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
  c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The `PARTITION_EXPRESSION` column in a `PARTITIONS` table record for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)
```

- `SUBPARTITION_EXPRESSION`: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as `PARTITION_EXPRESSION` does for the partitioning expression used to define a table’s partitioning.

If the table has no subpartitions, then this column is `NULL`.

- `PARTITION_DESCRIPTION`: This column is used for `RANGE` and `LIST` partitions. For a `RANGE` partition, it contains the value set in the partition’s `VALUES LESS THAN` clause, which can be either an integer or `MAXVALUE`. For a `LIST` partition, this column contains the values defined in the partition’s `VALUES IN` clause, which is a comma-separated list of integer values.

For partitions whose `PARTITION_METHOD` is other than `RANGE` or `LIST`, this column is always `NULL`.

- `TABLE_ROWS`: The number of table rows in the partition.

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column is only an estimated value used in SQL optimization, and may not always be exact.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `AVG_ROW_LENGTH`: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as `DATA_LENGTH` divided by `TABLE_ROWS`.

You can also obtain equivalent information using the `ndb_desc` utility.

- `DATA_LENGTH`: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `MAX_DATA_LENGTH`: The maximum number of bytes that can be stored in this partition or subpartition.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `INDEX_LENGTH`: The length of the index file for this partition or subpartition, in bytes.

For partitions of `NDB` tables, whether the tables use implicit or explicit partitioning, the `INDEX_LENGTH` column value is always 0. However, you can obtain equivalent information using the `ndb_desc` utility.

- `DATA_FREE`: The number of bytes allocated to the partition or subpartition but not used.

For `NDB` tables, you can also obtain this information using the `ndb_desc` utility.

- `CREATE_TIME`: The time of the partition's or subpartition's creation.
- `UPDATE_TIME`: The time that the partition or subpartition was last modified.
- `CHECK_TIME`: The last time that the table to which this partition or subpartition belongs was checked.

Note

Some storage engines do not update this time; for tables using these storage engines, this value is always `NULL`.

- `CHECKSUM`: The checksum value, if any; otherwise, this column is `NULL`.
- `PARTITION_COMMENT`: This column contains the text of any comment made for the partition.

In MySQL 5.5, the display width of this column is 80 characters, and partition comments which exceed this length are truncated to fit. This issue is fixed in MySQL 5.6. (Bug #11748924, Bug #37728)

The default value for this column is an empty string.

- `NODEGROUP`: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- `TABLESPACE_NAME`: This column contains the name of the tablespace to which the partition belongs. Currently, the value of this column is always `DEFAULT`.
- A nonpartitioned table has one record in `INFORMATION_SCHEMA.PARTITIONS`; however, the values of the `PARTITION_NAME`, `SUBPARTITION_NAME`, `PARTITION_ORDINAL_POSITION`, `SUBPARTITION_ORDINAL_POSITION`, `PARTITION_METHOD`, `SUBPARTITION_METHOD`, `PARTITION_EXPRESSION`, `SUBPARTITION_EXPRESSION`, and `PARTITION_DESCRIPTION` columns are all `NULL`. (The `PARTITION_COMMENT` column in this case is blank.)

In MySQL 5.5, there is also only one record in the `PARTITIONS` table for a table using the `NDBCLUSTER` storage engine. The same columns are also `NULL` (or empty) as for a nonpartitioned table.

20.13. The `INFORMATION_SCHEMA PLUGINS` Table

The `PLUGINS` table provides information about server plugins.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|-----------------|
| <code>PLUGIN_NAME</code> | Name | MySQL extension |
| <code>PLUGIN_VERSION</code> | | MySQL extension |
| <code>PLUGIN_STATUS</code> | Status | MySQL extension |
| <code>PLUGIN_TYPE</code> | Type | MySQL extension |
| <code>PLUGIN_TYPE_VERSION</code> | | MySQL extension |
| <code>PLUGIN_LIBRARY</code> | Library | MySQL extension |
| <code>PLUGIN_LIBRARY_VERSION</code> | | MySQL extension |
| <code>PLUGIN_AUTHOR</code> | | MySQL extension |
| <code>PLUGIN_DESCRIPTION</code> | | MySQL extension |
| <code>PLUGIN_LICENSE</code> | | MySQL extension |
| <code>LOAD_OPTION</code> | | MySQL extension |

Notes:

- The `PLUGINS` table is a nonstandard table.
- `PLUGIN_NAME` is the name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- `PLUGIN_VERSION` is the version from the plugin's general type descriptor.
- `PLUGIN_STATUS` indicates the plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- `PLUGIN_TYPE` indicates the type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- `PLUGIN_TYPE_VERSION` is the version from the plugin's type-specific descriptor.
- `PLUGIN_LIBRARY` is the name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` [537] system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- `PLUGIN_LIBRARY_VERSION` indicates the plugin API interface version.
- `PLUGIN_AUTHOR` names the plugin author.
- `PLUGIN_DESCRIPTION` provides a short description of the plugin.
- `PLUGIN_LICENSE` indicates how the plugin is licensed; for example, `GPL`.
- `LOAD_OPTION` indicates how the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See Section 5.1.8.1, "Installing and Uninstalling Plugins". This column was added in MySQL 5.5.7.

For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.

These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
```

```

    PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;

```

For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [Section 23.2, “The MySQL Plugin API”](#).

Plugin information is also available using the `SHOW PLUGINS` statement. See [Section 13.7.5.26, “SHOW PLUGINS Syntax”](#).

20.14. The `INFORMATION_SCHEMA.PROCESSLIST` Table

The `PROCESSLIST` table provides information about which threads are running.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|-----------------|
| ID | Id | MySQL extension |
| USER | User | MySQL extension |
| HOST | Host | MySQL extension |
| DB | db | MySQL extension |
| COMMAND | Command | MySQL extension |
| TIME | Time | MySQL extension |
| STATE | State | MySQL extension |
| INFO | Info | MySQL extension |

For an extensive description of the table columns, see [Section 13.7.5.30, “SHOW PROCESSLIST Syntax”](#).

Notes:

- The `PROCESSLIST` table is a nonstandard table.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS [696]` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```

SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST

SHOW FULL PROCESSLIST

```

20.15. The `INFORMATION_SCHEMA.PROFILING` Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 13.7.5.32, “SHOW PROFILES Syntax”](#)). The table is empty unless the `profiling [539]` session variable is set to 1.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---------|
| QUERY_ID | Query_ID | |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|---------------------|---------|
| SEQ | | |
| STATE | Status | |
| DURATION | Duration | |
| CPU_USER | CPU_user | |
| CPU_SYSTEM | CPU_system | |
| CONTEXT_VOLUNTARY | Context_voluntary | |
| CONTEXT_INVOLUNTARY | Context_involuntary | |
| BLOCK_OPS_IN | Block_ops_in | |
| BLOCK_OPS_OUT | Block_ops_out | |
| MESSAGES_SENT | Messages_sent | |
| MESSAGES_RECEIVED | Messages_received | |
| PAGE_FAULTS_MAJOR | Page_faults_major | |
| PAGE_FAULTS_MINOR | Page_faults_minor | |
| SWAPS | Swaps | |
| SOURCE_FUNCTION | Source_function | |
| SOURCE_FILE | Source_file | |
| SOURCE_LINE | Source_line | |

Notes:

- `QUERY_ID` is a numeric statement identifier.
- `SEQ` is a sequence number indicating the display order for rows with the same `QUERY_ID` value.
- `STATE` is the profiling state to which the row measurements apply.
- `DURATION` indicates how long statement execution remained in the given state, in seconds.
- `CPU_USER` and `CPU_SYSTEM` indicate user and system CPU use, in seconds.
- `CONTEXT_VOLUNTARY` and `CONTEXT_INVOLUNTARY` indicate how many voluntary and involuntary context switches occurred.
- `BLOCK_OPS_IN` and `BLOCK_OPS_OUT` indicate the number of block input and output operations.
- `MESSAGES_SENT` and `MESSAGES_RECEIVED` indicate the number of communication messages sent and received.
- `PAGE_FAULTS_MAJOR` and `PAGE_FAULTS_MINOR` indicate the number of major and minor page faults.
- `SWAPS` indicates how many swaps occurred.
- `SOURCE_FUNCTION`, `SOURCE_FILE`, and `SOURCE_LINE` provide information indicating where in the source code the profiled state executes.

20.16. The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The REFERENTIAL_CONSTRAINTS table provides information about foreign keys.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|---------------------------|-----------|---------|
| CONSTRAINT_CATALOG | | def |
| CONSTRAINT_SCHEMA | | |
| CONSTRAINT_NAME | | |
| UNIQUE_CONSTRAINT_CATALOG | | def |
| UNIQUE_CONSTRAINT_SCHEMA | | |
| UNIQUE_CONSTRAINT_NAME | | |
| MATCH_OPTION | | |
| UPDATE_RULE | | |
| DELETE_RULE | | |
| TABLE_NAME | | |
| REFERENCED_TABLE_NAME | | |

Notes:

- TABLE_NAME has the same value as TABLE_NAME in INFORMATION_SCHEMA.TABLE_CONSTRAINTS.
- CONSTRAINT_SCHEMA and CONSTRAINT_NAME identify the foreign key.
- UNIQUE_CONSTRAINT_SCHEMA, UNIQUE_CONSTRAINT_NAME, and REFERENCED_TABLE_NAME identify the referenced key.
- The only valid value at this time for MATCH_OPTION is NONE.
- The possible values for UPDATE_RULE or DELETE_RULE are CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.

20.17. The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (both procedures and functions). The ROUTINES table does not include user-defined functions (UDFs).

The column named “mysql.proc name” indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA.ROUTINES table column, if any.

| INFORMATION_SCHEMA Name | mysql.proc Name | Remarks |
|--------------------------|-----------------|---------------------------|
| SPECIFIC_NAME | specific_name | |
| ROUTINE_CATALOG | | def |
| ROUTINE_SCHEMA | db | |
| ROUTINE_NAME | name | |
| ROUTINE_TYPE | type | {PROCEDURE FUNCTION} |
| DATA_TYPE | | same as for COLUMNS table |
| CHARACTER_MAXIMUM_LENGTH | | same as for COLUMNS table |
| CHARACTER_OCTET_LENGTH | | same as for COLUMNS table |
| NUMERIC_PRECISION | | same as for COLUMNS table |

| INFORMATION_SCHEMA Name | mysql.proc Name | Remarks |
|-------------------------|------------------|---------------------------|
| NUMERIC_SCALE | | same as for COLUMNS table |
| CHARACTER_SET_NAME | | same as for COLUMNS table |
| COLLATION_NAME | | same as for COLUMNS table |
| DTD_IDENTIFIER | | data type descriptor |
| ROUTINE_BODY | | SQL |
| ROUTINE_DEFINITION | body_utf8 | |
| EXTERNAL_NAME | | NULL |
| EXTERNAL_LANGUAGE | language | NULL |
| PARAMETER_STYLE | | SQL |
| IS_DETERMINISTIC | is_deterministic | |
| SQL_DATA_ACCESS | sql_data_access | |
| SQL_PATH | | NULL |
| SECURITY_TYPE | security_type | |
| CREATED | created | |
| LAST_ALTERED | modified | |
| SQL_MODE | sql_mode [556] | MySQL extension |
| ROUTINE_COMMENT | comment | MySQL extension |
| DEFINER | definer | MySQL extension |
| CHARACTER_SET_CLIENT | | MySQL extension |
| COLLATION_CONNECTION | | MySQL extension |
| DATABASE_COLLATION | | MySQL extension |

Notes:

- MySQL calculates EXTERNAL_LANGUAGE thus:
 - If `mysql.proc.language='SQL'`, EXTERNAL_LANGUAGE is NULL
 - Otherwise, EXTERNAL_LANGUAGE is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always NULL.
- CHARACTER_SET_CLIENT is the session value of the `character_set_client` [486] system variable when the routine was created. COLLATION_CONNECTION is the session value of the `collation_connection` [489] system variable when the routine was created. DATABASE_COLLATION is the collation of the database with which the routine is associated.
- The DATA_TYPE, CHARACTER_MAXIMUM_LENGTH, CHARACTER_OCTET_LENGTH, NUMERIC_PRECISION, NUMERIC_SCALE, CHARACTER_SET_NAME, and COLLATION_NAME columns provide information about the data type for the RETURNS clause of stored functions. If a stored routine is a stored procedure, these columns all are NULL. These columns were added in MySQL 5.5.3.
- Information about stored function RETURNS data types is also available in the PARAMETERS table. The return value data type row for a function can be identified as the row that has an ORDINAL_POSITION value of 0.

20.18. The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|---|------------------------|----------|
| <code>CATALOG_NAME</code> | | def |
| <code>SCHEMA_NAME</code> | | Database |
| <code>DEFAULT_CHARACTER_SET_NAME</code> | | |
| <code>DEFAULT_COLLATION_NAME</code> | | |
| <code>SQL_PATH</code> | | NULL |

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
[LIKE 'wild']
```

20.19. The `INFORMATION_SCHEMA` `SCHEMA_PRIVILEGES` Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|--|
| <code>GRANTEE</code> | | ' <i>user_name</i> '@' <i>host_name</i> ' value, MySQL extension |
| <code>TABLE_CATALOG</code> | | def, MySQL extension |
| <code>TABLE_SCHEMA</code> | | MySQL extension |
| <code>PRIVILEGE_TYPE</code> | | MySQL extension |
| <code>IS_GRANTABLE</code> | | MySQL extension |

Notes:

- This is a nonstandard table. It takes its values from the `mysql.db` table.

20.20. The `INFORMATION_SCHEMA` `STATISTICS` Table

The `STATISTICS` table provides information about table indexes.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|------------|
| <code>TABLE_CATALOG</code> | | def |
| <code>TABLE_SCHEMA</code> | | = Database |
| <code>TABLE_NAME</code> | Table | |
| <code>NON_UNIQUE</code> | Non_unique | |
| <code>INDEX_SCHEMA</code> | | = Database |
| <code>INDEX_NAME</code> | Key_name | |
| <code>SEQ_IN_INDEX</code> | Seq_in_index | |
| <code>COLUMN_NAME</code> | Column_name | |
| <code>COLLATION</code> | Collation | |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-------------|-----------------|
| CARDINALITY | Cardinality | |
| SUB_PART | Sub_part | MySQL extension |
| PACKED | Packed | MySQL extension |
| NULLABLE | Null | MySQL extension |
| INDEX_TYPE | Index_type | MySQL extension |
| COMMENT | Comment | MySQL extension |

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
     AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

20.21. The INFORMATION_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------------|---|
| TABLE_CATALOG | | def |
| TABLE_SCHEMA | Table_... | |
| TABLE_NAME | Table_... | |
| TABLE_TYPE | | |
| ENGINE | Engine | MySQL extension |
| VERSION | Version | The version number of the table's <code>.frm</code> file, MySQL extension |
| ROW_FORMAT | Row_format | MySQL extension |
| TABLE_ROWS | Rows | MySQL extension |
| AVG_ROW_LENGTH | Avg_row_length | MySQL extension |
| DATA_LENGTH | Data_length | MySQL extension |
| MAX_DATA_LENGTH | Max_data_length | MySQL extension |
| INDEX_LENGTH | Index_length | MySQL extension |
| DATA_FREE | Data_free | MySQL extension |
| AUTO_INCREMENT | Auto_increment | MySQL extension |

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|-----------------------------|-----------------|
| <code>CREATE_TIME</code> | <code>Create_time</code> | MySQL extension |
| <code>UPDATE_TIME</code> | <code>Update_time</code> | MySQL extension |
| <code>CHECK_TIME</code> | <code>Check_time</code> | MySQL extension |
| <code>TABLE_COLLATION</code> | <code>Collation</code> | MySQL extension |
| <code>CHECKSUM</code> | <code>Checksum</code> | MySQL extension |
| <code>CREATE_OPTIONS</code> | <code>Create_options</code> | MySQL extension |
| <code>TABLE_COMMENT</code> | <code>Comment</code> | MySQL extension |

Notes:

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. Currently, the `TABLES` table does not list `TEMPORARY` tables.
- For partitioned tables, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database.

For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- For `NDB` tables, `DATA_LENGTH` includes data stored in main memory only; the `MAX_DATA_LENGTH` and `DATA_FREE` columns apply to Disk Data.
- For MySQL Cluster Disk Data tables, `MAX_DATA_LENGTH` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)
- The `DATA_FREE` column shows the free space in bytes for `InnoDB` tables.

For MySQL Cluster, `DATA_FREE` shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)

- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
- The `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']

SHOW TABLES
FROM db_name
[LIKE 'wild']
```

20.22. The `INFORMATION_SCHEMA TABLESPACES` Table

The `TABLESPACES` table provides information about active tablespaces. The table was added in MySQL 5.5.3.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|-----------------|
| TABLESPACE_NAME | | MySQL extension |
| ENGINE | | MySQL extension |
| TABLESPACE_TYPE | | MySQL extension |
| LOGFILE_GROUP_NAME | | MySQL extension |
| EXTENT_SIZE | | MySQL extension |
| AUTOEXTEND_SIZE | | MySQL extension |
| MAXIMUM_SIZE | | MySQL extension |
| NODEGROUP_ID | | MySQL extension |
| TABLESPACE_COMMENT | | MySQL extension |

20.23. The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| CONSTRAINT_CATALOG | | def |
| CONSTRAINT_SCHEMA | | |
| CONSTRAINT_NAME | | |
| TABLE_SCHEMA | | |
| TABLE_NAME | | |
| CONSTRAINT_TYPE | | |

Notes:

- The CONSTRAINT_TYPE value can be UNIQUE, PRIMARY KEY, or FOREIGN KEY.
- The UNIQUE and PRIMARY KEY information is about the same as what you get from the Key_name field in the output from SHOW INDEX when the Non_unique field is 0.
- The CONSTRAINT_TYPE column can contain one of these values: UNIQUE, PRIMARY KEY, FOREIGN KEY, CHECK. This is a CHAR (not ENUM) column. The CHECK value is not available until we support CHECK.

20.24. The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The TABLE_PRIVILEGES table provides information about table privileges. This information comes from the mysql.tables_priv grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|-------------------------------|
| GRANTEE | | 'user_name'@'host_name' value |
| TABLE_CATALOG | | def |
| TABLE_SCHEMA | | |
| TABLE_NAME | | |
| PRIVILEGE_TYPE | | |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| IS_GRANTABLE | | |

Notes:

- PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT [697], INSERT [696], UPDATE [697], REFERENCES [696], ALTER [695], INDEX [696], DROP [696], CREATE VIEW [696].

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

20.25. The INFORMATION_SCHEMA TRIGGERS Table

The TRIGGERS table provides information about triggers. You can see results only for databases and tables for which you have the TRIGGER [697] privilege.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|----------------------------|-----------|-----------------|
| TRIGGER_CATALOG | | def |
| TRIGGER_SCHEMA | | |
| TRIGGER_NAME | Trigger | |
| EVENT_MANIPULATION | Event | |
| EVENT_OBJECT_CATALOG | | def |
| EVENT_OBJECT_SCHEMA | | |
| EVENT_OBJECT_TABLE | Table | |
| ACTION_ORDER | | 0 |
| ACTION_CONDITION | | NULL |
| ACTION_STATEMENT | Statement | |
| ACTION_ORIENTATION | | ROW |
| ACTION_TIMING | Timing | |
| ACTION_REFERENCE_OLD_TABLE | | NULL |
| ACTION_REFERENCE_NEW_TABLE | | NULL |
| ACTION_REFERENCE_OLD_ROW | | OLD |
| ACTION_REFERENCE_NEW_ROW | | NEW |
| CREATED | | NULL (0) |
| SQL_MODE | | MySQL extension |
| DEFINER | | MySQL extension |
| CHARACTER_SET_CLIENT | | MySQL extension |
| COLLATION_CONNECTION | | MySQL extension |
| DATABASE_COLLATION | | MySQL extension |

Notes:

- The TRIGGER_SCHEMA and TRIGGER_NAME columns contain the name of the database in which the trigger occurs and the trigger name, respectively.

- The `EVENT_MANIPULATION` column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.
- As noted in [Section 19.3, “Using Triggers”](#), every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.
- The `ACTION_ORDER` column contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.
- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value 'ROW'.
- The `ACTION_TIMING` column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value 'OLD' and `ACTION_REFERENCE_NEW_ROW` always contains the value 'NEW'.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` [556] system variable. See [Section 5.1.7, “Server SQL Modes”](#).
- The `DEFINER` column indicates who defined the trigger.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` [486] system variable when the trigger was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` [489] system variable when the trigger was created. `DATABASE_COLLATION` is the collation of the database with which the trigger is associated.
- The following columns currently always contain NULL: `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, `ACTION_REFERENCE_NEW_TABLE`, and `CREATED`.

Example, using the `ins_sum` trigger defined in [Section 19.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
      TRIGGER_CATALOG: def
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: def
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 0
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: NULL
      SQL_MODE:
      DEFINER: me@localhost
```

See also [Section 13.7.5.39](#), “`SHOW TRIGGERS Syntax`”.

20.26. The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|--|
| GRANTEE | | ' <i>user_name</i> '@' <i>host_name</i> ' value, MySQL extension |
| TABLE_CATALOG | | <i>def</i> , MySQL extension |
| PRIVILEGE_TYPE | | MySQL extension |
| IS_GRANTABLE | | MySQL extension |

Notes:

- This is a nonstandard table. It takes its values from the `mysql.user` table.

20.27. The INFORMATION_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` [\[697\]](#) privilege to access this table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|-----------------|
| TABLE_CATALOG | | <i>def</i> |
| TABLE_SCHEMA | | |
| TABLE_NAME | | |
| VIEW_DEFINITION | | |
| CHECK_OPTION | | |
| IS_UPDATABLE | | |
| DEFINER | | |
| SECURITY_TYPE | | |
| CHARACTER_SET_CLIENT | | MySQL extension |
| COLLATION_CONNECTION | | MySQL extension |

Notes:

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column has a value of `NONE`, `CASCADE`, or `LOCAL`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 13.1.20](#), “`CREATE VIEW Syntax`”.)
- The `DEFINER` column indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` [486] system variable when the view was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` [489] system variable when the view was created.

MySQL lets you use different `sql_mode` [556] settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` [617] SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` [556] setting to a value different from `ANSI` [617] could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` [1102] function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
       -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` [556] will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

20.28. INFORMATION_SCHEMA Tables for InnoDB

The `InnoDB` tables related to the `InnoDB` storage engine help you to monitor ongoing `InnoDB` activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues that do occur. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly. The monitoring information deals with:

- `InnoDB` table compression, a feature whose use depends on a balance between I/O reduction, CPU usage, buffer pool management, and how much compression is possible for your data.
- Transactions and locks, features that balance high performance for a single operation, against the ability to run multiple operations concurrently. (Transactions are the high-level, user-visible aspect of concurrency. Locks are the low-level mechanism that transactions use to avoid reading or writing unreliable data.)

20.28.1. The `INFORMATION_SCHEMA INNODB_CMP` and `INNODB_CMP_RESET` Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information on operations related to compressed `InnoDB` tables.

Table 20.1. Columns of `INNODB_CMP` and `INNODB_CMP_RESET`

| Column name | Description |
|------------------------------|---|
| <code>PAGE_SIZE</code> | Compressed page size in bytes. |
| <code>COMPRESS_OPS</code> | Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out. |
| <code>COMPRESS_OPS_OK</code> | Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been successfully compressed. This count should never exceed <code>COMPRESS_OPS</code> . |
| <code>COMPRESS_TIME</code> | Total time in seconds spent in attempts to compress B-tree pages of the size <code>PAGE_SIZE</code> . |
| <code>UNCOMPRESS_OPS</code> | Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool. |
| <code>UNCOMPRESS_TIME</code> | Total time in seconds spent in uncompressing B-tree pages of the size <code>PAGE_SIZE</code> . |

Notes:

- Use these tables to measure the effectiveness of `InnoDB` table compression in your database.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.4.6.1.3, “Using the Compression Information Schema Tables”](#).

20.28.2. The `INFORMATION_SCHEMA INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` Tables

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information on compressed pages within the `InnoDB` buffer pool.

Table 20.2. Columns of `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET`

| Column name | Description |
|-----------------------------|---|
| <code>PAGE_SIZE</code> | Block size in bytes. Each record of this table describes blocks of this size. |
| <code>PAGES_USED</code> | Number of blocks of the size <code>PAGE_SIZE</code> that are currently in use. |
| <code>PAGES_FREE</code> | Number of blocks of the size <code>PAGE_SIZE</code> that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1. |
| <code>RELOCATION_OPS</code> | Number of times a block of the size <code>PAGE_SIZE</code> has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the table <code>INNODB_CMPMEM_RESET</code> resets this count. |

| Column name | Description |
|------------------------------|---|
| <code>RELOCATION_TIME</code> | Total time in microseconds spent in relocating blocks of the size <code>PAGE_SIZE</code> . Reading from the table <code>INNODB_CMPMEM_RESET</code> resets this count. |

Notes:

- Use these tables to measure the effectiveness of `InnoDB` table compression in your database.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.4.6.1.3, “Using the Compression Information Schema Tables”](#).

20.28.3. The `INFORMATION_SCHEMA INNODB_TRX` Table

The `INNODB_TRX` table contains information about every transaction currently executing inside `InnoDB`, including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing.

Table 20.3. `INNODB_TRX` Columns

| Column name | Description |
|------------------------------------|---|
| <code>TRX_ID</code> | Unique transaction ID number, internal to <code>InnoDB</code> . (Starting in MySQL 5.6, these IDs are not created for transactions that are read-only and non-locking. See Optimizations for Read-Only Transactions for details.) |
| <code>TRX_WEIGHT</code> | The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, <code>InnoDB</code> selects the transaction with the smallest weight as the “victim” to rollback. Transactions that have changed non-transactional tables are considered heavier than others, regardless of the number of altered and locked rows. |
| <code>TRX_STATE</code> | Transaction execution state. One of <code>RUNNING</code> , <code>LOCK WAIT</code> , <code>ROLLING BACK</code> or <code>COMMITTING</code> . |
| <code>TRX_STARTED</code> | Transaction start time. |
| <code>TRX_REQUESTED_LOCK_ID</code> | ID of the lock the transaction is currently waiting for (if <code>TRX_STATE</code> is <code>LOCK WAIT</code> , otherwise <code>NULL</code>). Details about the lock can be found by joining with <code>INNODB_LOCKS</code> on <code>LOCK_ID</code> . |
| <code>TRX_WAIT_STARTED</code> | Time when the transaction started waiting on the lock (if <code>TRX_STATE</code> is <code>LOCK WAIT</code> , otherwise <code>NULL</code>). |
| <code>TRX_MYSQL_THREAD_ID</code> | MySQL thread ID. Can be used for joining with <code>PROCESSLIST</code> on <code>ID</code> . See Section 14.4.6.3.3, “Possible Inconsistency with <code>PROCESSLIST</code>” . |
| <code>TRX_QUERY</code> | The SQL query that is being executed by the transaction. |
| <code>TRX_OPERATION_STATE</code> | The transaction's current operation, or <code>NULL</code> . |
| <code>TRX_TABLES_IN_USE</code> | The number of <code>InnoDB</code> tables used while processing the current SQL statement of this transaction. |
| <code>TRX_TABLES_LOCKED</code> | Number of <code>InnoDB</code> tables that currently have any locks. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.) |

| Column name | Description |
|----------------------------|---|
| TRX_LOCK_STRUCTS | The number of locks reserved by the transaction. |
| TRX_LOCK_MEMORY_BYTES | Total size taken up by the lock structures of this transaction in memory. |
| TRX_ROWS_LOCKED | Approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction. |
| TRX_ROWS_MODIFIED | The number of modified and inserted rows in this transaction. |
| TRX_CONCURRENCY_TICKETS | A value indicating how much work the current transaction can do before being swapped out, as specified by the <code>innodb_concurrency_tickets</code> option. |
| TRX_ISOLATION_LEVEL | The isolation level of the current transaction. |
| TRX_UNIQUE_CHECKS | Whether unique checks are turned on or off for the current transaction. (They might be turned off during a bulk data load, for example.) |
| TRX_FOREIGN_KEY_CHECKS | Whether foreign key checks are turned on or off for the current transaction. (They might be turned off during a bulk data load, for example.) |
| TRX_LAST_FOREIGN_KEY_ERROR | Detailed error message for last FK error, or <code>NULL</code> . |
| TRX_ADAPTIVE_HASH_LATCHED | Whether or not the adaptive hash index is locked by the current transaction. (Only a single transaction at a time can modify the adaptive hash index.) |
| TRX_ADAPTIVE_HASH_TIMEOUT | Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no AHI contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup. |
| TRX_IS_READ_ONLY | A value of 1 indicates the transaction is read-only. (5.6.4 and up.) |
| TRX_AUTOCOMMIT_NON_LOCKING | A value of 1 indicates the transaction is a <code>SELECT</code> statement that does not use the <code>FOR UPDATE</code> or <code>LOCK IN SHARED MODE</code> clauses, and is executing with the <code>autocommit</code> setting turned on so that the transaction will only contain this one statement. (5.6.4 and up.) When this column and <code>TRX_IS_READ_ONLY</code> are both 1, <code>InnoDB</code> optimizes the transaction to reduce the overhead associated with transactions that change table data. |

Notes:

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.4.6.2.4, “Using the Transaction Information Schema Tables”](#).

20.28.4. The INFORMATION_SCHEMA INNODB_LOCKS Table

The `INNODB_LOCKS` table contains information about each lock that an `InnoDB` transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

Table 20.4. `INNODB_LOCKS` Columns

| Column name | Description |
|--------------------------|--|
| <code>LOCK_ID</code> | Unique lock ID number, internal to <code>InnoDB</code> . Treat it as an opaque string. Although <code>LOCK_ID</code> currently contains <code>TRX_ID</code> , the format of the data in <code>LOCK_ID</code> is not guaranteed to remain the same in future releases. Do not write programs that parse the <code>LOCK_ID</code> value. |
| <code>LOCK_TRX_ID</code> | ID of the transaction holding this lock. Details about the transaction can be found by joining with <code>INNODB_TRX</code> on <code>TRX_ID</code> . |
| <code>LOCK_MODE</code> | Mode of the lock. One of <code>S</code> , <code>X</code> , <code>IS</code> , <code>IX</code> , <code>S_GAP</code> , <code>X_GAP</code> , <code>IS_GAP</code> , <code>IX_GAP</code> , or <code>AUTO_INC</code> for shared, exclusive, intention shared, intention exclusive row locks, shared and exclusive gap locks, intention shared and intention exclusive gap locks, and auto-increment table level lock, respectively. Refer to the sections Section 14.3.9.1, “InnoDB Lock Modes” and Section 14.3.9, “The InnoDB Transaction Model and Locking” for information on <code>InnoDB</code> locking. |
| <code>LOCK_TYPE</code> | Type of the lock. One of <code>RECORD</code> or <code>TABLE</code> for record (row) level or table level locks, respectively. |
| <code>LOCK_TABLE</code> | Name of the table that has been locked or contains locked records. |
| <code>LOCK_INDEX</code> | Name of the index if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> . |
| <code>LOCK_SPACE</code> | Tablespace ID of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> . |
| <code>LOCK_PAGE</code> | Page number of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> . |
| <code>LOCK_REC</code> | Heap number of the locked record within the page if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> . |
| <code>LOCK_DATA</code> | Primary key of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> . This column contains the value(s) of the primary key column(s) in the locked row, formatted as a valid SQL string (ready to be copied to SQL commands). If there is no primary key then the <code>InnoDB</code> internal unique row ID number is used. When the page containing the locked record is not in the buffer pool (in the case that it was paged out to disk while the lock was held), <code>InnoDB</code> does not fetch the page from disk, to avoid unnecessary disk operations. Instead, <code>LOCK_DATA</code> is set to <code>NULL</code> . |

Notes:

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.4.6.2.4, “Using the Transaction Information Schema Tables”](#).

20.28.5. The `INFORMATION_SCHEMA.INNODB_LOCK_WAITS` Table

The `INNODB_LOCK_WAITS` table contains one or more rows for each blocked `InnoDB` transaction, indicating the lock it has requested and any locks that are blocking that request.

Table 20.5. `INNODB_LOCK_WAITS` Columns

| Column name | Description |
|--------------------------------|--|
| <code>REQUESTING_TRX_ID</code> | ID of the requesting transaction. |
| <code>REQUESTED_LOCK_ID</code> | ID of the lock for which a transaction is waiting. Details about the lock can be found by joining with <code>INNODB_LOCKS</code> on <code>LOCK_ID</code> . |
| <code>BLOCKING_TRX_ID</code> | ID of the blocking transaction. |

| Column name | Description |
|-------------------------------|--|
| <code>BLOCKING_LOCK_ID</code> | ID of a lock held by a transaction blocking another transaction from proceeding. Details about the lock can be found by joining with <code>INNODB_LOCKS</code> on <code>LOCK_ID</code> . |

Notes:

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.4.6.2.4, “Using the Transaction Information Schema Tables”](#).

20.28.6. The `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` Table

The `INNODB_BUFFER_PAGE` table holds information about each `page` in the `InnoDB` buffer pool.

Table 20.6. `INNODB_BUFFER_PAGE` Columns

| Column name | Description |
|----------------------------------|--|
| <code>POOL_ID</code> | Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances. |
| <code>BLOCK_ID</code> | Buffer Pool Block ID. |
| <code>SPACE</code> | Tablespace ID. Uses the same value as in <code>INNODB_SYS_TABLES.SPACE</code> . |
| <code>PAGE_NUMBER</code> | Page number. |
| <code>PAGE_TYPE</code> | Page type string. One of <code>allocated</code> (Freshly allocated page), <code>index</code> (B-tree node), <code>undo_log</code> (Undo log page), <code>inode</code> (Index node), <code>ibuf_free_list</code> (Insert buffer free list), <code>ibuf_bitmap</code> (Insert buffer bitmap), <code>system</code> (System page), <code>trx_system</code> (Transaction system data), <code>file_space_header</code> (File space header), <code>extent_descriptor</code> (Extent descriptor page), <code>blob</code> (Uncompressed BLOB page), <code>compressed_blob</code> (First compressed BLOB page), <code>compressed_blob2</code> (Subsequent comp BLOB page), <code>unknown</code> (unknown). |
| <code>FLUSH_TYPE</code> | Flush type. |
| <code>FIX_COUNT</code> | Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted. |
| <code>IS_HASHED</code> | Whether hash index has been built on this page. |
| <code>NEWEST_MODIFICATION</code> | Log Sequence Number of the youngest modification. |
| <code>OLDEST_MODIFICATION</code> | Log Sequence Number of the oldest modification. |
| <code>ACCESS_TIME</code> | Time of first access. |
| <code>TABLE_NAME</code> | Name of the table the page belongs to. |
| <code>INDEX_NAME</code> | Name of the index the page belongs to. It can be the name of a clustered index or a secondary index. |
| <code>NUMBER_RECORDS</code> | Number of records within the page. |
| <code>DATA_SIZE</code> | Sum of the sizes of the records. |
| <code>COMPRESSED_SIZE</code> | Compressed page size. Null for pages that are not compressed. |
| <code>PAGE_STATE</code> | Page state. A page with valid data has one of the following states: <code>FILE_PAGE</code> (buffers a page of data from a file), <code>MEMORY</code> (buffers a page |

| Column name | Description |
|------------------------------|---|
| | from an in-memory object), Other possible states (managed by <code>InnoDB</code>) are: null, <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> . |
| <code>IO_FIX</code> | Specifies whether any I/O is pending for this page: <code>IO_NONE</code> = no pending I/O, <code>IO_READ</code> = read pending, <code>IO_WRITE</code> = write pending. |
| <code>IS_OLD</code> | <code>bpage->old</code> . |
| <code>FREE_PAGE_CLOCK</code> | <code>bpage->freed_page_clock</code> . |

Notes:

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- You must have the `PROCESS` privilege to query this table.

20.28.7. The `INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU` Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full.

The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of `BLOCK_ID`.

Notes:

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes time the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
 - Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.

20.28.8. The `INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS` Table

The `INNODB_BUFFER_POOL_STATS` table represents the same kinds of `InnoDB` buffer pool information as the output from `SHOW ENGINE INNODB STATUS`.

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the `sublists` at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of `eviction`.

Column meanings in this table are intended to be self-explanatory for developers who formerly parsed the `SHOW ENGINE INNODB STATUS` to get these values.

Table 20.7. INNODB_BUFFER_POOL_STATS Columns

| Column name | Description |
|----------------------------------|-------------|
| POOL_ID | |
| POOL_SIZE | |
| FREE_BUFFERS | |
| DATABASE_PAGES | |
| OLD_DATABASE_PAGES | |
| MODIFIED_DATABASE_PAGES | |
| PENDING_DECOMPRESS | |
| PENDING_READS | |
| PENDING_FLUSH_LRU | |
| PENDING_FLUSH_LIST | |
| PAGES_MADE_YOUNG | |
| PAGES_NOT_MADE_YOUNG | |
| PAGES_MADE_YOUNG_RATE | |
| PAGES_MADE_NOT_YOUNG_RATE | |
| NUMBER_PAGES_READ | |
| NUMBER_PAGES_CREATED | |
| NUMBER_PAGES_WRITTEN | |
| PAGES_READ_RATE | |
| PAGES_CREATE_RATE | |
| PAGES_WRITTEN_RATE | |
| NUMBER_PAGES_GET | |
| HIT_RATE | |
| YOUNG_MAKE_PER_THOUSAND_GETS | |
| NOT_YOUNG_MAKE_PER_THOUSAND_GETS | |
| NUMBER_PAGES_READ_AHEAD | |
| NUMBER_READ_AHEAD_EVICTED | |
| READ_AHEAD_RATE | |
| READ_AHEAD_EVICTED_RATE | |
| LRU_IO_TOTAL | |
| LRU_IO_CURRENT | |
| UNCOMPRESS_TOTAL | |
| UNCOMPRESS_CURRENT | |

Notes:

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Since the `INFORMATION_SCHEMA` is a general-purpose way to monitor the MySQL server, use this table rather than the corresponding `InnoDB` system table for any new monitoring application you develop.

- You must have the `PROCESS` privilege to query this table.

20.29. INFORMATION_SCHEMA Tables for MySQL Cluster

The following sections provide information about `INFORMATION_SCHEMA` tables which are specific to MySQL Cluster. The `FILES` table was added in MySQL Server 5.1.6 as part of MySQL Cluster data-on-disk support (it is available in standard MySQL 5.5 but is not used there). The `ndb_transid_mysql_connection_map` table was added as part of additions made to MySQL Cluster's `ndbinfo` information database in MySQL Cluster NDB 7.2.2; it is implemented as an `INFORMATION_SCHEMA` plugin available only in MySQL Cluster binaries or source, and does not exist in MySQL Server 5.5.

Additional statistical and other data about MySQL Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. Information about these tables, see [Section 17.5.10, “The `ndbinfo` MySQL Cluster Information Database”](#).

20.29.1. The INFORMATION_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL NDB Disk Data tables are stored.

Note

This table provides information about Disk Data *files* only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, it is possible to see how much space is allocated for each NDB table having data stored on disk—as well as how much remains available for storage of data on disk for that table—using `ndb_desc`. For more information, see [Section 17.4.9, “`ndb_desc` — Describe NDB Tables”](#).

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-----------------------------------|-----------|-----------------|
| <code>FILE_ID</code> | | MySQL extension |
| <code>FILE_NAME</code> | | MySQL extension |
| <code>FILE_TYPE</code> | | MySQL extension |
| <code>TABLESPACE_NAME</code> | | MySQL extension |
| <code>TABLE_CATALOG</code> | | MySQL extension |
| <code>TABLE_SCHEMA</code> | | MySQL extension |
| <code>TABLE_NAME</code> | | MySQL extension |
| <code>LOGFILE_GROUP_NAME</code> | | MySQL extension |
| <code>LOGFILE_GROUP_NUMBER</code> | | MySQL extension |
| <code>ENGINE</code> | | MySQL extension |
| <code>FULLTEXT_KEYS</code> | | MySQL extension |
| <code>DELETED_ROWS</code> | | MySQL extension |
| <code>UPDATE_COUNT</code> | | MySQL extension |
| <code>FREE_EXTENTS</code> | | MySQL extension |
| <code>TOTAL_EXTENTS</code> | | MySQL extension |
| <code>EXTENT_SIZE</code> | | MySQL extension |
| <code>INITIAL_SIZE</code> | | MySQL extension |
| <code>MAXIMUM_SIZE</code> | | MySQL extension |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-------------|-----------------|
| AUTOEXTEND_SIZE | | MySQL extension |
| CREATION_TIME | | MySQL extension |
| LAST_UPDATE_TIME | | MySQL extension |
| LAST_ACCESS_TIME | | MySQL extension |
| RECOVER_TIME | | MySQL extension |
| TRANSACTION_COUNTER | | MySQL extension |
| VERSION | | MySQL extension |
| ROW_FORMAT | | MySQL extension |
| TABLE_ROWS | | MySQL extension |
| AVG_ROW_LENGTH | | MySQL extension |
| DATA_LENGTH | | MySQL extension |
| MAX_DATA_LENGTH | | MySQL extension |
| INDEX_LENGTH | | MySQL extension |
| DATA_FREE | | MySQL extension |
| CREATE_TIME | CREATE_TIME | MySQL extension |
| UPDATE_TIME | | MySQL extension |
| CHECK_TIME | | MySQL extension |
| CHECKSUM | | MySQL extension |
| STATUS | | MySQL extension |
| EXTRA | | MySQL extension |

Notes:

- `FILE_ID` column values are auto-generated.
- `FILE_NAME` is the name of an `UNDO` log file created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`.
- `FILE_TYPE` is one of the values `UNDOFILE`, `DATAFILE`, or `TABLESPACE`.
- `TABLESPACE_NAME` is the name of the tablespace with which the file is associated.
- Currently, the value of the `TABLESPACE_CATALOG` column is always `NULL`.
- `TABLE_NAME` is the name of the Disk Data table with which the file is associated, if any.
- The `LOGFILE_GROUP_NAME` column gives the name of the log file group to which the log file or data file belongs.
- For an `UNDO` log file, the `LOGFILE_GROUP_NUMBER` contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the `ENGINE` column is always `NDB` or `NDBCLUSTER`.
- For a MySQL Cluster Disk Data log file or data file, the value of the `FULLTEXT_KEYS` column is always empty.

- The `FREE_EXTENTS` column displays the number of extents which have not yet been used by the file. The `TOTAL_EXTENTS` column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. See [Section 13.1.18, “CREATE TABLESPACE Syntax”](#), for more information.

- The `INITIAL_SIZE` column shows the size in bytes of the file. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

For MySQL Cluster Disk Data files, the value of the `MAXIMUM_SIZE` column is always the same as `INITIAL_SIZE`, and the `AUTOEXTEND_SIZE` column is always empty.

- The `CREATION_TIME` column shows the date and time when the file was created. The `LAST_UPDATE_TIME` column displays the date and time when the file was last modified. The `LAST_ACCESSED` column provides the date and time when the file was last accessed by the server.

Currently, the values of these columns are as reported by the operating system, and are not supplied by the `NDB` storage engine. Where no value is provided by the operating system, these columns display `0000-00-00 00:00:00`.

- For MySQL Cluster Disk Data files, the value of the `RECOVER_TIME` and `TRANSACTION_COUNTER` columns is always `0`.
- For MySQL Cluster Disk Data files, the following columns are always `NULL`:
 - `VERSION`
 - `ROW_FORMAT`

- TABLE_ROWS
- AVG_ROW_LENGTH
- DATA_LENGTH
- MAX_DATA_LENGTH
- INDEX_LENGTH
- DATA_FREE
- CREATE_TIME
- UPDATE_TIME
- CHECK_TIME
- CHECKSUM
- For MySQL Cluster Disk Data files, the value of the STATUS column is always NORMAL.
- For MySQL Cluster Disk Data files, the EXTRA column shows which data node the file belongs to, as each data node has its own copy of the file. Suppose that you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
  ENGINE NDB;
```

After running the CREATE LOGFILE GROUP statement successfully, you should see a result similar to the one shown here for this query against the FILES table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'new_undo.dat';
```

| LOGFILE_GROUP_NAME | FILE_TYPE | EXTRA |
|--------------------|-----------|----------------|
| mygroup | UNDO FILE | CLUSTER_NODE=3 |
| mygroup | UNDO FILE | CLUSTER_NODE=4 |
| mygroup | UNDO FILE | CLUSTER_NODE=5 |
| mygroup | UNDO FILE | CLUSTER_NODE=6 |

4 rows in set (0.01 sec)

- The FILES table is a nonstandard table.
- An additional row is present in the FILES table following the creation of a logfile group. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always UNDO FILE, and that of the STATUS column is always NORMAL. Currently, the value of the ENGINE column is always NDBCLUSTER.

The FREE_EXTENTS column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the LOGFILE_GROUP_NAME and LOGFILE_GROUP_NUMBER columns, respectively.

Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile.dat'
-> INITIAL_SIZE = 16M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE = NDB;
Query OK, 0 rows affected (3.81 sec)
```

You can now see this NULL row when you query the FILES table:

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
+-----+-----+-----+-----+-----+
| File          | Free    | Total  | Size | Initial |
+-----+-----+-----+-----+-----+
| undofile.dat  | NULL    | 4194304 | 4    | 16777216 |
| NULL          | 4184068 | NULL    | 4    | NULL    |
+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

The total number of free extents available for undo logging is always somewhat less than the sum of the TOTAL_EXTENTS column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the FILES table:

```
mysql> ALTER LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile02.dat'
-> INITIAL_SIZE = 4M
-> ENGINE = NDB;
Query OK, 0 rows affected (1.02 sec)

mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
+-----+-----+-----+-----+-----+
| File          | Free    | Total  | Size | Initial |
+-----+-----+-----+-----+-----+
| undofile.dat  | NULL    | 4194304 | 4    | 16777216 |
| undofile02.dat | NULL    | 1048576 | 4    | 4194304  |
| NULL          | 5223944 | NULL    | 4    | NULL    |
+-----+-----+-----+-----+-----+
3 rows in set (0.01 sec)
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5223944     | 20895776  |
+-----+-----+
```

```
+-----+-----+
1 row in set (0.02 sec)
```

If you create a MySQL Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```
mysql> CREATE TABLESPACE ts1
->   ADD DATAFILE 'data1.dat'
->   USE LOGFILE GROUP lg1
->   INITIAL_SIZE 512M
->   ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)

mysql> CREATE TABLE dd (
->   c1 INT NOT NULL PRIMARY KEY,
->   c2 INT,
->   c3 DATE
-> )
-> TABLESPACE ts1 STORAGE DISK
-> ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
-> (NULL, 1234567890, '2007-02-02'),
-> (NULL, 1126789005, '2007-02-03'),
-> (NULL, 1357924680, '2007-02-04'),
-> (NULL, 1642097531, '2007-02-05');
Query OK, 4 rows affected (0.01 sec)

mysql> SELECT
->   FREE_EXTENTS AS 'Free Extents',
->   FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
|          5207565 |      20830260 |
+-----+-----+
1 row in set (0.01 sec)
```

- An additional row is present in the `FILES` table for any MySQL Cluster tablespace, whether or not any data files are associated with the tablespace. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always 0, that of the `FILE_TYPE` column is always `TABLESPACE`, and that of the `STATUS` column is always `NORMAL`. Currently, the value of the `ENGINE` column is always `NDBCLUSTER`.
- There are no `SHOW` statements associated with the `FILES` table.
- For additional information, and examples of creating and dropping MySQL Cluster Disk Data objects, see [Section 17.5.12, “MySQL Cluster Disk Data Tables”](#).

20.29.2. The `INFORMATION_SCHEMA` `ndb_transid_mysql_connection_map` Table

The `ndb_transid_mysql_connection_map` table provides a mapping between `NDB` transactions, `NDB` transaction coordinators, and MySQL Servers attached to a MySQL Cluster as API nodes. This information is used when populating the `server_operations` and `server_transactions` tables of the `ndbinfo` MySQL Cluster information database.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------------------------------|
| mysql_connection_id | | MySQL Server connection ID |
| node_id | | Transaction coordinator node ID |
| ndb_transid | | NDB transaction ID |

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`.

There are no `SHOW` statements associated with this table.

This is a nonstandard table, added in MySQL Cluster NDB 7.2.2. It is implemented as an `INFORMATION_SCHEMA` plugin; you can verify that it is supported by checking the output of `SHOW PLUGINS`. If `ndb_transid_mysql_connection_map` support is enabled, the output from this statement includes a plugin having this name, of type `INFORMATION_SCHEMA`, and having status `ACTIVE`, as shown here (using emphasized text):

```
mysql> SHOW PLUGINS;
```

| Name | Status | Type | Library | License |
|---|---------------|---------------------------|-------------|------------|
| binlog | ACTIVE | STORAGE ENGINE | NULL | GPL |
| mysql_native_password | ACTIVE | AUTHENTICATION | NULL | GPL |
| mysql_old_password | ACTIVE | AUTHENTICATION | NULL | GPL |
| CSV | ACTIVE | STORAGE ENGINE | NULL | GPL |
| MEMORY | ACTIVE | STORAGE ENGINE | NULL | GPL |
| MRG_MYISAM | ACTIVE | STORAGE ENGINE | NULL | GPL |
| MyISAM | ACTIVE | STORAGE ENGINE | NULL | GPL |

```

The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the `--ndb-transid-mysql-connection-map` [2145] option. If the plugin is disabled, the status is shown by `SHOW PLUGINS` as `DISABLED`. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary that was supplied with the MySQL Cluster distribution, or one that was built from the MySQL Cluster sources with `NDB` storage engine support enabled. It is not available in the standard MySQL 5.5 Server.

20.30. Thread Pool `INFORMATION_SCHEMA` Tables

The following sections describe the `INFORMATION_SCHEMA` tables associated with the thread pool plugin. They provide information about thread pool operation:

- `TP_THREAD_STATE`: Information about thread pool thread states
- `TP_THREAD_GROUP_STATE`: Information about thread pool thread group states
- `TP_THREAD_GROUP_STATS`: Thread group statistics

Rows in these tables represent snapshots in time. In the case of `TP_THREAD_STATE`, all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against `TP_THREAD_STATE` from blocking the entire MySQL server.

The thread pool `INFORMATION_SCHEMA` tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see [Section 8.11.6.1, “Thread Pool Components and Installation”](#)). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed but will be empty.

20.30.1. The `INFORMATION_SCHEMA TP_THREAD_STATE` Table

This table has one row per thread created by the thread pool to handle connections. The table has these columns:

- `TP_GROUP_ID`

The thread group ID.

- `TP_THREAD_NUMBER`

The ID of the thread within its thread group. `TP_GROUP_ID` and `TP_THREAD_NUMBER` together provide a unique key within the table.

- `PROCESS_COUNT`

The 10ms interval in which the statement that uses this thread is currently executing. 0 means no statement is executing, 1 means it is in the first 10ms, and so forth.

- `WAIT_TYPE`

The type of wait for the thread. `NULL` means the thread is not blocked. Otherwise, the thread is blocked by a call to `thd_wait_begin()` and the value specifies the type of wait. The `xxx_WAIT` columns of the `TP_THREAD_GROUP_STATS` table accumulate counts for each wait type.

The `WAIT_TYPE` value is a string that describes the type of wait, as shown in the following table.

Table 20.8. `WAIT_TYPE` Values

| Wait Type | Meaning |
|-----------------------------------|-------------------------|
| <code>THD_WAIT_SLEEP</code> | Waiting for sleep |
| <code>THD_WAIT_DISKIO</code> | Waiting for Disk IO |
| <code>THD_WAIT_ROW_LOCK</code> | Waiting for row lock |
| <code>THD_WAIT_GLOBAL_LOCK</code> | Waiting for global lock |

| Wait Type | Meaning |
|--------------------------------------|---------------------------|
| <code>THD_WAIT_META_DATA_LOCK</code> | Waiting for metadata lock |
| <code>THD_WAIT_TABLE_LOCK</code> | Waiting for table lock |
| <code>THD_WAIT_USER_LOCK</code> | Waiting for user lock |
| <code>THD_WAIT_BINLOG</code> | Waiting for binlog |
| <code>THD_WAIT_GROUP_COMMIT</code> | Waiting for group commit |
| <code>THD_WAIT_SYNC</code> | Waiting for fsync |

20.30.2. The `INFORMATION_SCHEMA TP_THREAD_GROUP_STATE` Table

This table has one row per thread group in the thread pool. Each row provides information about the current state of a group. The table has these columns:

- `TP_GROUP_ID`

The thread group ID. This is a unique key within the table.

- `CONSUMER_THREADS`

The number of consumer threads. There is at most one thread ready to start executing if the active threads become stalled or blocked.

- `RESERVE_THREADS`

The number of threads in the reserved state. This means that they will not be started until there is a need to wake a new thread and there is no consumer thread. This is where most threads end up when the thread group has created more threads than needed for normal operation. Often a thread group needs additional threads for a short while and then does not need them again for a while. In this case, they go into the reserved state and remain until needed again. They take up some extra memory resources, but no extra computing resources.

- `CONNECTION_COUNT`

The number of connections using this thread group.

- `QUEUED_QUERIES`

The number of statements waiting in the high-priority queue.

- `QUEUED_TRANSACTIONS`

The number of statements waiting in the low-priority queue. These are the initial statements for transactions that have not started, so they also represent queued transactions.

- `STALL_LIMIT`

The value of the `thread_pool_stall_limit` [566] variable on the thread group. This is the same value for all thread groups.

- `PRIO_KICKUP_TIMER`

The value of the `thread_pool_prio_kickup_timer` [565] on the thread group. This is the same value for all thread groups.

- `ALGORITHM`

The value of the `thread_pool_algorithm` [563] on the thread group. This is the same value for all thread groups.

- `THREAD_COUNT`

The number of threads started in the thread pool as part of this thread group.

- `ACTIVE_THREAD_COUNT`

The number of threads active executing statements.

- `MAX_THREAD_IDS_IN_GROUP`

The maximum thread ID of the threads in the group. This is the same as `MAX(TP_THREAD_NUMBER)` [1205] for the threads when selected from the `TP_THREAD_GROUP_STATE` table. That is, these two queries are equivalent:

```
SELECT TP_GROUP_ID, MAX_THREAD_IDS_IN_GROUP
FROM TP_THREAD_GROUP_STATE;

SELECT TP_GROUP_ID, MAX(TP_THREAD_NUMBER)
FROM TP_THREAD_STATE GROUP BY TP_GROUP_ID;
```

- `STALLED_THREAD_COUNT`

The number of stalled statements in the thread group. A stalled statement could be executing, but from a thread pool perspective it is stalled and making no progress. A long-running statement quickly ends up in this category.

- `WAITING_THREAD_NUMBER`

If there is a thread handling the polling of statements in the thread group, this specifies the thread number within this thread group. It is possible that this thread could be executing a statement.

- `OLDEST_QUEUED`

How long in milliseconds the oldest queued statement has been waiting for execution.

20.30.3. The `INFORMATION_SCHEMA TP_THREAD_GROUP_STATS` Table

This table reports statistics per thread group. There is one row per group. The table has these columns:

- `TP_GROUP_ID`

The thread group ID. This is a unique key within the table.

- `CONNECTIONS_STARTED`

The number of connections started.

- `CONNECTIONS_CLOSED`

The number of connections closed.

- `QUERIES_EXECUTED`

The number of statements executed. This number is incremented when a statement starts executing, not when it finishes.

- [QUERIES_QUEUED](#)

The number of statements received that were queued for execution. This does not count statements that the thread group was able to begin executing immediately without queuing, which can happen under the conditions described in [Section 8.11.6.2, “Thread Pool Operation”](#).

- [THREADS_STARTED](#)

The number of threads started.

- [PRIO_KICKUPS](#)

The number of statements that have been moved from low-priority queue to high-priority queue based on the value of the [thread_pool_prio_kickup_timer \[565\]](#) system variable. If this number increases quickly, consider increasing the value of that variable. A quickly increasing counter means that the priority system is not keeping transactions from starting too early. For [InnoDB](#), this most likely means deteriorating performance due to too many concurrent transactions..

- [STALLED_QUERIES_EXECUTED](#)

The number of statements that have become defined as stalled due to executing for a time longer than the value of the [thread_pool_stall_limit \[566\]](#) system variable.

- [BECOME_CONSUMER_THREAD](#)

The number of times thread have been assigned the consumer thread role.

- [BECOME_RESERVE_THREAD](#)

The number of times threads have been assigned the reserve thread role.

- [BECOME_WAITING_THREAD](#)

The number of times threads have been assigned the waiter thread role. When statements are queued, this happens very often, even in normal operation, so rapid increases in this value are normal in the case of a highly loaded system where statements are queued up.

- [WAKE_THREAD_STALL_CHECKER](#)

The number of times the stall check thread decided to wake or create a thread to possibly handle some statements or take care of the waiter thread role.

- [SLEEP_WAITS](#)

The number of [THD_WAIT_SLEEP](#) waits. These occur when threads go to sleep; for example, by calling the [SLEEP \(\) \[1201\]](#) function.

- [DISK_IO_WAITS](#)

The number of [THD_WAIT_DISKIO](#) waits. These occur when threads perform disk I/O that is likely to not hit the file system cache. Such waits occur when the buffer pool reads and writes data to disk, not for normal reads from and writes to files.

- [ROW_LOCK_WAITS](#)

The number of [THD_WAIT_ROW_LOCK](#) waits for release of a row lock by another transaction.

- [GLOBAL_LOCK_WAITS](#)

The number of `THD_WAIT_GLOBAL_LOCK` waits for a global lock to be released.

- `META_DATA_LOCK_WAITS`

The number of `THD_WAIT_META_DATA_LOCK` waits for a metadata lock to be released.

- `TABLE_LOCK_WAITS`

The number of `THD_WAIT_TABLE_LOCK` waits for a table to be unlocked that the statement needs to access.

- `USER_LOCK_WAITS`

The number of `THD_WAIT_USER_LOCK` waits for a special lock constructed by the user thread.

- `BINLOG_WAITS`

The number of `THD_WAIT_BINLOG_WAITS` waits for the binary log to become free.

- `GROUP_COMMIT_WAITS`

The number of `THD_WAIT_GROUP_COMMIT` waits. These occur when a group commit must wait for the other parties to complete their part of a transaction.

- `FSYNC_WAITS`

The number of `THD_WAIT_SYNC` waits for a file sync operation.

20.31. Extensions to `SHOW` Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
```

```
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS              |
| COLLATIONS                  |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                    |
| COLUMN_PRIVILEGES           |
| ENGINES                     |
| EVENTS                      |
| FILES                       |
| GLOBAL_STATUS               |
| GLOBAL_VARIABLES           |
| KEY_COLUMN_USAGE            |
| PARTITIONS                  |
| PLUGINS                     |
| PROCESSLIST                 |
```

```

| REFERENTIAL_CONSTRAINTS
| ROUTINES
| SCHEMATA
| SCHEMA_PRIVILEGES
| SESSION_STATUS
| SESSION_VARIABLES
| STATISTICS
| TABLES
| TABLE_CONSTRAINTS
| TABLE_PRIVILEGES
| TRIGGERS
| USER_PRIVILEGES
| VIEWS
+-----+
27 rows in set (0.00 sec)

```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE [1111]` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```

SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES

```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```

mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description                | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese   | big5_chinese_ci  | 2      |
| dec8    | DEC West European         | dec8_swedish_ci  | 1      |
| cp850   | DOS West European         | cp850_general_ci | 1      |
| hp8     | HP West European          | hp8_english_ci   | 1      |
| koi8r   | KOI8-R Relcom Russian     | koi8r_general_ci | 1      |
| latin1  | cp1252 West European      | latin1_swedish_ci | 1      |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1      |
...

```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```

mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description                | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis    | EUC-JP Japanese           | ujis_japanese_ci  | 3      |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci  | 2      |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2      |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3      |
+-----+-----+-----+-----+

```

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
```

| Charset | Description | Default collation | Maxlen |
|---------|---------------------------|---------------------|--------|
| big5 | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ujis | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| euckr | EUC-KR Korean | euckr_korean_ci | 2 |
| gb2312 | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| gbk | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| utf8 | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2 | UCS-2 Unicode | ucs2_general_ci | 2 |
| cp932 | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |

Chapter 21. MySQL Performance Schema

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema is available as of MySQL 5.5.3 and has these characteristics:

- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the `PERFORMANCE_SCHEMA` storage engine and the `performance_schema` database. The Performance Schema focuses primarily on performance data. This differs from `INFORMATION_SCHEMA`, which serves for inspection of metadata.
- The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Currently, event collection provides access to information about synchronization calls (such as for mutexes) and file I/O calls for the server and for several storage engines.
- Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).
- Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.
- The `PERFORMANCE_SCHEMA` storage engine collects event data using “instrumentation points” in server source code.
- Collected events are stored in tables in the `performance_schema` database. These tables can be queried using `SELECT` statements like other tables.

- Performance Schema configuration can be modified dynamically by updating tables in the `performance_schema` database through SQL statements. Configuration changes affect data collection immediately.
- Tables in the `performance_schema` database are views or temporary tables that use no persistent on-disk storage.
- Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also [Section E.8, “Restrictions on Performance Schema”](#).

- Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by `EXPLAIN`) to change.
- No memory allocation is done beyond that which occurs during server startup. By using early allocation of structures with a fixed size, it is never necessary to resize or reallocate them, which is critical for achieving good runtime performance.
- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.
- The parser is unchanged. There are no new keywords or statements.
- Execution of server code proceeds normally even if the Performance Schema fails internally.
- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code will continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

21.1. Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see [Section 21.11, “Using the Performance Schema to Diagnose Problems”](#).

For the Performance Schema to be available, support for it must have been configured when MySQL was built. You can verify whether this is the case by checking the server's help output. If the Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysqld --verbose --help
...
```

```
--performance_schema
    Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
    Number of rows in events_waits_history_long.
...
```

If such variables do not appear in the output, your server has not been built to support the Performance Schema. In this case, see [Section 21.2, “Performance Schema Configuration”](#).

Assuming that the Performance Schema is available, it is disabled by default. To enable it, start the server with the `performance_schema` [\[2554\]](#) variable enabled. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema
```

When the server starts, it sees `performance_schema` [\[2554\]](#) and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON    |
+-----+-----+
```

A value of `ON` means that the Performance Schema initialized successfully and is ready for use. A value of `OFF` means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a `SUPPORT` value of `YES` in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE='PERFORMANCE_SCHEMA'\G
***** 1. row *****
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO

mysql> SHOW ENGINES\G
...
Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
XA: NO
Savepoints: NO
...
```

The `PERFORMANCE_SCHEMA` storage engine operates on tables in the `performance_schema` database. You can make `performance_schema` the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Many examples in this chapter assume that `performance_schema` is the default database.

Performance Schema tables are stored in the `performance_schema` database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from

the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'performance_schema';
+-----+
| TABLE_NAME |
+-----+
| cond_instances |
| events_waits_current |
| events_waits_history |
| events_waits_history_long |
| events_waits_summary_by_instance |
| events_waits_summary_by_thread_by_event_name |
| events_waits_summary_global_by_event_name |
| file_instances |
| file_summary_by_event_name |
| file_summary_by_instance |
| mutex_instances |
| performance_timers |
| rwlock_instances |
| setup_consumers |
| setup_instruments |
| setup_timers |
| threads |
+-----+

mysql> SHOW TABLES FROM performance_schema;
+-----+
| Tables_in_performance_schema |
+-----+
| cond_instances |
| events_waits_current |
| events_waits_history |
| ... |
+-----+
```

The number of Performance Schema tables is expected to increase over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Note

Before MySQL 5.5.8, the table names were uppercase, which caused problems on some systems for certain values of the `lower_case_table_names` [518] system variable.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE setup_timers\G
***** 1. row *****
      Table: setup_timers
Create Table: CREATE TABLE `setup_timers` (
  `NAME` varchar(64) NOT NULL,
  `TIMER_NAME` enum('CYCLE','NANOSECOND','MICROSECOND','MILLISECOND','TICK')
  NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8
```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration)

information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see [Section 21.7, “Performance Schema Table Descriptions”](#).

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:

```
mysql> SELECT * FROM events_waits_current\G
***** 1. row *****
      THREAD_ID: 0
      EVENT_ID: 5523
      EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
      SOURCE: thr_lock.c:525
      TIMER_START: 201660494489586
      TIMER_END: 201660494576112
      TIMER_WAIT: 86526
      SPINS: NULL
      OBJECT_SCHEMA: NULL
      OBJECT_NAME: NULL
      OBJECT_TYPE: NULL
      OBJECT_INSTANCE_BEGIN: 142270668
      NESTING_EVENT_ID: NULL
      OPERATION: lock
      NUMBER_OF_BYTES: NULL
      FLAGS: 0
...

```

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- `EVENT_NAME` indicates what was instrumented and `SOURCE` indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the `TIMER_END` and `TIMER_WAIT` values are `NULL`. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```
mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
-> FROM events_waits_history WHERE THREAD_ID = 13
-> ORDER BY EVENT_ID;
+-----+-----+-----+
| EVENT_ID | EVENT_NAME | TIMER_WAIT |
+-----+-----+-----+
| 86 | wait/synch/mutex/mysys/THR_LOCK::mutex | 686322 |
| 87 | wait/synch/mutex/mysys/THR_LOCK_malloc | 320535 |
| 88 | wait/synch/mutex/mysys/THR_LOCK_malloc | 339390 |
| 89 | wait/synch/mutex/mysys/THR_LOCK_malloc | 377100 |
| 90 | wait/synch/mutex/sql/LOCK_plugin | 614673 |
| 91 | wait/synch/mutex/sql/LOCK_open | 659925 |
| 92 | wait/synch/mutex/sql/THD::LOCK_thd_data | 494001 |
| 93 | wait/synch/mutex/mysys/THR_LOCK_malloc | 222489 |
| 94 | wait/synch/mutex/mysys/THR_LOCK_malloc | 214947 |
| 95 | wait/synch/mutex/mysys/LOCK_alarm | 312993 |
+-----+-----+-----+

```

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```
mysql> SELECT EVENT_NAME, COUNT_STAR
-> FROM events_waits_summary_global_by_event_name
-> ORDER BY COUNT_STAR DESC LIMIT 10;
```

| EVENT_NAME | COUNT_STAR |
|---|------------|
| wait/synch/mutex/mysys/THR_LOCK_malloc | 6419 |
| wait/io/file/sql/FRM | 452 |
| wait/synch/mutex/sql/LOCK_plugin | 337 |
| wait/synch/mutex/mysys/THR_LOCK_open | 187 |
| wait/synch/mutex/mysys/LOCK_alarm | 147 |
| wait/synch/mutex/sql/THD::LOCK_thd_data | 115 |
| wait/io/file/mysam/kfile | 102 |
| wait/synch/mutex/sql/LOCK_global_system_variables | 89 |
| wait/synch/mutex/mysys/THR_LOCK::mutex | 89 |
| wait/synch/mutex/sql/LOCK_open | 88 |

```
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
-> FROM events_waits_summary_global_by_event_name
-> ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
```

| EVENT_NAME | SUM_TIMER_WAIT |
|--|----------------|
| wait/io/file/sql/MYSQL_LOG | 1599816582 |
| wait/synch/mutex/mysys/THR_LOCK_malloc | 1530083250 |
| wait/io/file/sql/binlog_index | 1385291934 |
| wait/io/file/sql/FRM | 1292823243 |
| wait/io/file/mysam/kfile | 411193611 |
| wait/io/file/mysam/dfile | 322401645 |
| wait/synch/mutex/mysys/LOCK_alarm | 145126935 |
| wait/io/file/sql/casetest | 104324715 |
| wait/synch/mutex/sql/LOCK_plugin | 86027823 |
| wait/io/file/sql/pid | 72591750 |

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

Note

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```
mysql> SELECT * FROM file_instances\G
***** 1. row *****
FILE_NAME: /opt/mysql-log/60500/binlog.000007
EVENT_NAME: wait/io/file/sql/binlog
OPEN_COUNT: 0
***** 2. row *****
```

```

FILE_NAME: /opt/mysql/60500/data/mysql/tables_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
***** 3. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/columns_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
...

```

Setup tables are used to configure and display monitoring characteristics. For example, to see which event timer is selected, query the `setup_timers` tables:

```

mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | CYCLE      |
+-----+-----+

```

`setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```

mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager | YES     | YES   |
...
| wait/synch/rwlock/sql/LOCK_grant | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave | YES     | YES   |
...
| wait/io/file/sql/binlog | YES     | YES   |
| wait/io/file/sql/binlog_index | YES     | YES   |
| wait/io/file/sql/casetest | YES     | YES   |
| wait/io/file/sql/dbopt | YES     | YES   |
...

```

To understand how to interpret instrument names, see [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```

mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';

```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and shows which of them are enabled:

```

mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_waits_current | YES     |
| events_waits_history | YES     |
| events_waits_history_long | YES     |
| events_waits_summary_by_thread_by_event_name | YES     |

```

| | |
|------------------------------------|-----|
| events_waits_summary_by_event_name | YES |
| events_waits_summary_by_instance | YES |
| file_summary_by_event_name | YES |
| file_summary_by_instance | YES |

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see [Section 21.2.3.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

21.2. Performance Schema Configuration

To use the MySQL Performance Schema, these configuration considerations apply:

- The Performance Schema must be configured into MySQL Server at build time to make it available. Performance Schema support is included in binary MySQL distributions. If you are building from source, you must ensure that it is configured into the build as described in [Section 21.2.1, “Performance Schema Build Configuration”](#).
- The Performance Schema must be enabled at server startup to enable event collection to occur. Specific Performance Schema features can be enabled at server startup or at runtime to control which types of event collection occur. See [Section 21.2.2, “Performance Schema Startup Configuration”](#), [Section 21.2.3, “Performance Schema Runtime Configuration”](#), and [Section 21.2.3.2, “Performance Schema Event Filtering”](#).

21.2.1. Performance Schema Build Configuration

For the Performance Schema to be available, it must be configured into the MySQL server at build time. Binary MySQL distributions provided by Oracle Corporation are configured to support the Performance Schema. If you use a binary MySQL distribution from another provider, check with the provider whether the distribution has been appropriately configured.

If you build MySQL from a source distribution, enable the Performance Schema by running `CMake` with the `WITH_PERFSCHEMA_STORAGE_ENGINE` option enabled:

```
shell> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Configuring MySQL with the `-DWITHOUT_PERFSCHEMA_STORAGE_ENGINE=1` option prevents inclusion of the Performance Schema, so if you want it included, do not use this option. See [Section 2.10.4, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that may not have all the current tables), run `mysql_upgrade` after starting the server to ensure that the `performance_schema` database exists with all current tables. Then restart the server. One indication that you need to do this is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema`.`events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema`.`events_waits_history_long'
has the wrong structure
```

...

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysqld --verbose --help
...
--performance_schema
           Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
           Number of rows in events_waits_history_long.
...
```

You can also connect to the server and look for a line that names the `PERFORMANCE_SCHEMA` storage engine in the output from `SHOW ENGINES`:

```
mysql> SHOW ENGINES\G
...
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
  Transactions: NO
           XA: NO
  Savepoints: NO
...
```

If the Performance Schema was not configured into the server at build time, no row for `PERFORMANCE_SCHEMA` will appear in the output from `SHOW ENGINES`. You might see `performance_schema` listed in the output from `SHOW DATABASES`, but it will have no tables and you will not be able to use it.

A line for `PERFORMANCE_SCHEMA` in the `SHOW ENGINES` output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

21.2.2. Performance Schema Startup Configuration

The Performance Schema is disabled by default. To enable it, start the server with the `performance_schema` [2554] variable enabled. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` [2554] to `OFF`, and the server runs without instrumentation.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON |
| performance_schema_events_waits_history_long_size | 10000 |
| performance_schema_events_waits_history_size | 10 |
| performance_schema_max_cond_classes | 80 |
| performance_schema_max_cond_instances | 1000 |
| performance_schema_max_file_classes | 50 |
| performance_schema_max_file_handles | 32768 |
| performance_schema_max_file_instances | 10000 |
+-----+-----+
```

| | |
|---|---------|
| performance_schema_max_mutex_classes | 200 |
| performance_schema_max_mutex_instances | 1000000 |
| performance_schema_max_rwlock_classes | 30 |
| performance_schema_max_rwlock_instances | 1000000 |
| performance_schema_max_table_handles | 100000 |
| performance_schema_max_table_instances | 50000 |
| performance_schema_max_thread_classes | 50 |
| performance_schema_max_thread_instances | 1000 |

The `performance_schema` [2554] variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

Note

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. It may be necessary to tune the values of Performance Schema system variables to find the number of instances that balances insufficient instrumentation against excessive memory consumption.

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables:

```
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

21.2.3. Performance Schema Runtime Configuration

Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'performance_schema'
-> AND TABLE_NAME LIKE 'setup%';
+-----+
| TABLE_NAME |
+-----+
| setup_consumers |
| setup_instruments |
| setup_timers |
+-----+
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` [697] privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see [Section 21.7.1, “Performance Schema Setup Tables”](#).

To see which event timer is selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | CYCLE |
+-----+-----+
```

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with

a component matching the `NAME` value. Currently, there are only “wait” instruments, so this table has only one row and the timer applies to all instruments.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
      -> WHERE NAME = 'wait';

mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | NANOSECOND |
+-----+-----+
```

For discussion of timers, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. [Section 21.2.3.2, “Performance Schema Event Filtering”](#), discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like to these changes take effect each time the server starts, put the statements in a file and start the server with the `--init-file=file_name` [445] option. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `--init-file` [445] argument when you start the server.

21.2.3.1. Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

Two tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
- `setup_timers` indicates which timers are used for which instruments.

Each timer row in `setup_timers` must refer to one of the timers listed in `performance_timers`.

Timers vary in precision and the amount of overhead they involve. To see what timers are available and their characteristics, check the `performance_timers` table:

```
mysql> SELECT * FROM performance_timers;
+-----+-----+-----+-----+
| TIMER_NAME | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
+-----+-----+-----+-----+
| CYCLE | 2389029850 | 1 | 72 |
| NANOSECOND | NULL | NULL | NULL |
| MICROSECOND | 1000000 | 1 | 585 |
| MILLISECOND | 1035 | 1 | 738 |
| TICK | 101 | 1 | 630 |
+-----+-----+-----+-----+
```

The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter. If the values associated with a given timer name are `NULL`, that

timer is not supported on your platform. The rows that do not have `NULL` indicate which timers you can use in `setup_timers`.

`TIMER_FREQUENCY` indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For `TICK`, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).

`TIMER_RESOLUTION` indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.

`TIMER_OVERHEAD` is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timer is in effect or to change the timer, access the `setup_timers` table:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | CYCLE      |
+-----+-----+

mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
-> WHERE NAME = 'wait';

mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | MICROSECOND |
+-----+-----+
```

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one. Generally the best timer is `CYCLE`, which uses the CPU cycle counter whenever possible to provide high precision and low overhead.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard `gettimeofday()` function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.
- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.
- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is `RDTSC` (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.
- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

Currently, MySQL works with cycle counters on x386 (Windows, Mac OS X, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

Within events, times are stored in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected. The timer used for an event is the one in effect when event timing begins. This timer is used to convert start and end values to picoseconds for storage in the event.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress use the original timer for the begin time and the new timer for the end time, which leads to unpredictable results. If you make timer changes, you may want to use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline (“time zero”) occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

21.2.3.2. Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The `setup_instruments` table lists the instruments for which events can be collected, whether they are enabled, and whether to collect timing information:

```
mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager | YES     | YES   |
```

```

...
| wait/synch/rwlock/sql/LOCK_grant           | YES   | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger  | YES   | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES   | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave  | YES   | YES   |
...
| wait/io/file/sql/binlog                    | YES   | YES   |
| wait/io/file/sql/binlog_index              | YES   | YES   |
| wait/io/file/sql/casetest                  | YES   | YES   |
| wait/io/file/sql/dbopt                     | YES   | YES   |
...

```

- Performance Schema tables are the destinations for events and consume events. The `setup_consumers` table lists the types of consumers to which event information can be sent:

```

mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_waits_current                    | YES     |
| events_waits_history                     | YES     |
| events_waits_history_long                | YES     |
| events_waits_summary_by_thread_by_event_name | YES     |
| events_waits_summary_by_event_name       | YES     |
| events_waits_summary_by_instance         | YES     |
| file_summary_by_event_name               | YES     |
| file_summary_by_instance                 | YES     |
+-----+-----+

```

Filtering can be done at different stages of performance monitoring:

- **Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. This type of filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- Pre-filtering reduces overhead. The overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.
- You can avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.
- You can avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining it. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.
- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. This type of filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see [Section 21.3, “Performance Schema Queries”](#).

21.2.3.2.1. Event Pre-Filtering

Pre-filtering is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. This type of filtering is done by the Performance Schema and has a global effect that applies to all users.

Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To affect pre-filtering at the producer stage, modify the `setup_instruments` table. An instrument can be enabled or disabled by setting its `ENABLED` value to `YES` or `NO`. An instrument can be configured whether to collect timing information by setting its `TIMED` value to `YES` or `NO`.
- To affect pre-filtering at the consumer stage, modify the `setup_consumers` table. A consumer can be enabled or disabled by setting its `ENABLED` value to `YES` or `NO`.

Here are some examples that show the types of pre-filtering operations available:

- Disable all instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO';
```

Now no events will be collected. This change, like other pre-filtering operations, affects other users as well, even if they want to see event information.

- Disable all file instruments, adding them to the current set of disabled instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME LIKE 'wait/io/file/%';
```

- Disable only file instruments, enable all other instruments:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

The preceding queries use the `LIKE [1111]` operator and the pattern `'wait/io/file/%'` to match all instrument names that begin with `'wait/io/file/`. For additional information about specifying patterns to select instruments, see [Section 21.2.3.2.2, “Naming Instruments or Consumers for Filtering Operations”](#).

- Enable all but those instruments in the `mysys` library:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

- Disable a specific instrument:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
-> WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- Disable timing for all events:

```
mysql> UPDATE setup_instruments SET TIMED = 'NO';
```

Setting the `TIMED` column for instruments affects Performance Schema table contents as described in [Section 21.2.3.1, “Performance Schema Event Timing”](#).

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables as well to clear aggregate information for previously collected events. The effect of `TRUNCATE TABLE` for summary tables is to reset the summary columns to 0 or `NULL`, not to remove rows.

If you disable a consumer, the server does not spend time maintaining it. For example, you can disable the history table consumers if you do not care about historical event information:

```
mysql> UPDATE setup_consumers
-> SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

21.2.3.2.2. Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';

mysql> UPDATE setup_consumers
-> SET ENABLED = 'NO' WHERE NAME = 'file_summary_by_instance';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = 'NO'
-> WHERE NAME LIKE 'wait/synch/mutex/%';

mysql> UPDATE setup_consumers
-> SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```
... WHERE NAME LIKE 'wait/io/file/%';
```

A pattern of `'%/file/%'` will match other instruments that have a component of `'/file/'` anywhere in the name. Even less suitable is the pattern `'%file%'` because it will match instruments with `'file'` anywhere in the name, such as `wait/synch/mutex/sql/LOCK_des_key_file`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```
mysql> SELECT NAME FROM setup_instruments WHERE NAME LIKE 'pattern';

mysql> SELECT NAME FROM setup_consumers WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

21.2.3.3. Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the `InnoDB` storage engine, use this query:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'wait/io/file/innodb/%';
```

| NAME | ENABLED | TIMED |
|--------------------------------------|---------|-------|
| wait/io/file/innodb/innodb_data_file | YES | YES |
| wait/io/file/innodb/innodb_log_file | YES | YES |
| wait/io/file/innodb/innodb_temp_file | YES | YES |

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.
- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

21.3. Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In [Section 21.2.3.2.1, “Event Pre-Filtering”](#), an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
-> FROM events_waits_history
-> WHERE EVENT_NAME LIKE 'wait/io/file/%'
-> AND NUMBER_OF_BYTES IS NOT NULL;
```

| THREAD_ID | NUMBER_OF_BYTES |
|-----------|-----------------|
| 11 | 66 |
| 11 | 47 |
| 11 | 139 |
| 5 | 24 |
| 5 | 834 |

21.4. Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of components separated by `'/'` characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/synch/cond/mysys/COND_alarm
```

```
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/mutex/sql/LOCK_delete
wait/synch/rwlock/innodb/trx_sys_lock
wait/synch/rwlock/sql/Query_cache_query::lock
```

The instrument name space has a tree-like structure. The components of an instrument name from left to right provide a progression from more general to more specific. The number of components a name has depends on the type of instrument.

The interpretation of a given component in a name depends on the components to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/MI_SORT_INFO::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level component of an instrument prefix indicates the type of instrument. This component also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major component (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC:MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.

In MySQL 5.5, there is a single top-level component, `wait`, indicating a wait instrument. The naming tree for wait instruments has this structure:

- `wait/io`

An instrumented I/O operation.

- `wait/io/file`

An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- `wait/synch`

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- `wait/synch/cond`

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- `wait/synch/mutex`

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- `wait/synch/rwlock`

A read/write lock object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

21.5. Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Performance_schema_cond_classes_lost | 0 |
| Performance_schema_cond_instances_lost | 0 |
| Performance_schema_file_classes_lost | 0 |
| Performance_schema_file_handles_lost | 0 |
| Performance_schema_file_instances_lost | 0 |
| Performance_schema_locker_lost | 0 |
| Performance_schema_mutex_classes_lost | 0 |
| Performance_schema_mutex_instances_lost | 0 |
| Performance_schema_rwlock_classes_lost | 0 |
| Performance_schema_rwlock_instances_lost | 0 |
| Performance_schema_table_handles_lost | 0 |
| Performance_schema_table_instances_lost | 0 |
| Performance_schema_thread_classes_lost | 0 |
| Performance_schema_thread_instances_lost | 0 |
+-----+-----+
```

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- `Performance_schema_xxx_classes_lost` indicates how many instruments of type `xxx` could not be loaded.
- `Performance_schema_xxx_instances_lost` indicates how many instances of object type `xxx` could not be created.
- `Performance_schema_xxx_handles_lost` indicates how many instances of object type `xxx` could not be opened.
- `Performance_schema_locker_lost` indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments `Performance_schema_mutex_classes_lost` [2559]. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it will not be collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there will be only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers will increase the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost` [2559].

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` [2556] option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has $150+40 = 190$ mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for $200-190 = 10$ instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` [2559] indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| Performance_schema_mutex_classes_lost | 10    |
+-----+-----+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` [2559] increases by 1.
- `Performance_schema_mutex_instances_lost` [2559] does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` [2559] greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N` [2556], where `N` is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.

- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes` [2556].

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N` [2556], loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` [2556] is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database will miss events. The `Performance_schema_mutex_classes_lost` [2559] status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `Performance_schema_mutex_instances_lost` [2559] by 200 to indicate that instances could not be created.

A value of `Performance_schema_mutex_instances_lost` [2559] greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N` [2556].

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `Performance_schema_xxx_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory will be allocated for file-related classes, instances, or handles, and all file events will be lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.row_size
  Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.row_count
  Status: 10000
***** 5. row *****
  Type: performance_schema
```

```

Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
Type: performance_schema
Name: performance_schema.memory
Status: 26459600
...

```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see [Section 13.7.5.16](#), “`SHOW ENGINE Syntax`”.

21.6. Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Most tables in the `performance_schema` database are read only and cannot be modified. Some of the setup tables have columns that can be modified to affect Performance Schema operation. Truncation is permitted to clear collected events, so `TRUNCATE TABLE` can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

`TRUNCATE TABLE` can also be used with summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows.

Privileges are as for other databases and tables:

- To retrieve from `performance_schema` tables, you must have the `SELECT` [697] privilege.
- To change those columns that can be modified, you must have the `UPDATE` [697] privilege.
- To truncate tables that can be truncated, you must have the `DROP` [696] privilege.

21.7. Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events table. The `events_waits_current` table contains the most recent event for each thread.
- History tables. These tables have the same structure as `events_waits_current` but contain more rows. The `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events.

To change the sizes of these tables, set the

`performance_schema_events_waits_history_size` [2554] and `performance_schema_events_waits_history_long_size` [2554] system variables at server startup.

- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
- Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.

- Miscellaneous tables. These do not fall into any of the other table groups.

21.7.1. Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` [697] privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- `setup_consumers`: The types of consumers for which event information can be stored
- `setup_instruments`: The classes of instrumented objects for which events can be collected
- `setup_timers`: The current event timer

21.7.1.1. The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_waits_current                     | YES     |
| events_waits_history                     | YES     |
| events_waits_history_long                 | YES     |
| events_waits_summary_by_thread_by_event_name | YES     |
| events_waits_summary_by_event_name       | YES     |
| events_waits_summary_by_instance         | YES     |
| file_summary_by_event_name               | YES     |
| file_summary_by_instance                 | YES     |
+-----+-----+
```

The `setup_consumers` table has these columns:

- `NAME`
- `ENABLED`

The consumer name.

Whether the consumer is enabled. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

Disabling the `events_waits_current` consumer disables everything else that depends on waits, such as the `events_waits_history` and `events_waits_history_long` tables, and all summary tables.

21.7.1.2. The `setup_instruments` Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```
mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
```

```

+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock          | YES      | YES      |
| wait/synch/mutex/sql/LOCK_global_system_variables  | YES      | YES      |
| wait/synch/mutex/sql/LOCK_lock_db                  | YES      | YES      |
| wait/synch/mutex/sql/LOCK_manager                  | YES      | YES      |
...
| wait/synch/rwlock/sql/LOCK_grant                    | YES      | YES      |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger          | YES      | YES      |
| wait/synch/rwlock/sql/LOCK_sys_init_connect        | YES      | YES      |
| wait/synch/rwlock/sql/LOCK_sys_init_slave          | YES      | YES      |
...
| wait/io/file/sql/binlog                             | YES      | YES      |
| wait/io/file/sql/binlog_index                       | YES      | YES      |
| wait/io/file/sql/casetest                           | YES      | YES      |
| wait/io/file/sql/dbopt                             | YES      | YES      |
...

```

Each instrument added to the source code provides a row for this table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `*_instances` tables.

The `setup_instruments` table has these columns:

- **NAME**

The instrument name. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#). Events produced from execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- **ENABLED**

Whether the instrument is enabled. This column can be modified. A disabled instrument produces no events.

- **TIMED**

Whether the instrument is timed. This column can be modified.

If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

21.7.1.3. The `setup_timers` Table

The `setup_timers` table shows the currently selected event timer:

```

mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | CYCLE      |
+-----+-----+

```

The `setup_timers.TIMER_NAME` value can be changed to select a different timer. The value can be any of the values in the `performance_timers.TIMER_NAME` column. For an explanation of how event timing occurs, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

The `setup_timers` table has these columns:

- `NAME`

The type of instrument the timer is used for.

- `TIMER_NAME`

The timer that applies to the instrument type. This column can be modified.

The `setup_timers.TIMER_NAME` value can be changed to select a different timer. The value can be any of the values in the `performance_timers.TIMER_NAME` column. For an explanation of how event timing occurs, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress use the original timer for the begin time and the new timer for the end time, which leads to unpredictable results. If you make timer changes, you may want to use `TRUNCATE TABLE` to reset Performance Schema statistics.

21.7.2. Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- `cond_instances`: Condition synchronization object instances
- `file_instances`: File instances
- `mutex_instances`: Mutex synchronization object instances
- `rwlock_instances`: Lock synchronization object instances

These tables list instrumented synchronization objects and files. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see [Section 21.11, “Using the Performance Schema to Diagnose Problems”](#)

21.7.2.1. The `cond_instances` Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other thread, or threads, will cause the condition to happen.

The `cond_instances` table has these columns:

- `NAME`

The instrument name associated with the condition.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the condition that was instrumented.

21.7.2.2. The `file_instances` Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it will not be in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- `FILE_NAME`

The file name.

- `EVENT_NAME`

The instrument name associated with the file.

- `OPEN_COUNT`

The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` will be 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

21.7.2.3. The `mutex_instances` Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads will compete against each other, so that the first query to obtain a lock on the mutex will cause the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- `NAME`

The instrument name associated with the mutex.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the mutex that was instrumented.

- `LOCKED_BY_THREAD_ID`

When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.

- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.
- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).
- When a thread succeeds in locking a mutex:
 - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
 - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
 - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).
- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).
- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

21.7.2.4. The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` instances (read write locks) seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time) or exclusive (only one thread can have a write lock at a given time).

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, granted in exclusive mode, or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- `NAME`

The instrument name associated with the lock.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the lock that was instrumented.

- `WRITE_LOCKED_BY_THREAD_ID`

When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- `READ_LOCKED_BY_COUNT`

When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

21.7.3. Performance Schema Wait Event Tables

These tables store wait events:

- `events_waits_current`: Current wait events
- `events_waits_history`: The most recent wait events for each thread
- `events_waits_history_long`: The most recent wait events overall

21.7.3.1. The `events_waits_current` Table

The `events_waits_current` table contains current wait events, one row per thread showing the current status of the thread's most recent monitored wait event.

The `events_waits_current` table can be truncated with `TRUNCATE TABLE`.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events, up to a fixed number of rows.

The `events_waits_current` table has these columns:

- `THREAD_ID`

The thread associated with the event. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `EVENT_ID`

The thread current event number when the event starts.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `setup_instruments.NAME` value. Instrument names have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to

determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL`.

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

- `SPINS`

For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`, `OBJECT_INSTANCE_BEGIN`

These columns identify the object “being acted on.” What that means depends on the object type.

For a synchronization object (`cond`, `mutex`, `rwlock`):

- `OBJECT_SCHEMA`, `OBJECT_NAME`, and `OBJECT_TYPE` are `NULL`.
- `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

For a file I/O object:

- `OBJECT_SCHEMA` is `NULL`.
- `OBJECT_NAME` is the file name.
- `OBJECT_TYPE` is `FILE`.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- `NESTING_EVENT_ID`

Currently `NULL`.

- `OPERATION`

The type of operation performed, such as `lock`, `read`, or `write`.

- `NUMBER_OF_BYTES`

The number of bytes read or written by the operation.

- `FLAGS`

Reserved for future use.

21.7.3.2. The `events_waits_history` Table

The `events_waits_history` table contains the most recent 10 wait events per thread. The table size may be changed by modifying the `performance_schema_events_waits_history_size` [2554] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_waits_history` table has the same structure as `events_waits_current`. See [Section 21.7.3.1, “The `events_waits_current` Table”](#).

The `events_waits_history` table can be truncated with `TRUNCATE TABLE`.

21.7.3.3. The `events_waits_history_long` Table

The `events_waits_history_long` table contains the most recent 10,000 wait events. The table size may be changed by modifying the `performance_schema_events_waits_history_long_size` [2554] system variable at server startup. As new events are added to the table, older events are discarded if the table is full. Events are not added to the table until they have ended.

The `events_waits_history_long` table has the same structure as `events_waits_current`. See [Section 21.7.3.1, “The `events_waits_current` Table”](#).

The `events_waits_history_long` table can be truncated with `TRUNCATE TABLE`.

21.7.4. Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

Event Wait Summaries:

- `events_waits_summary_global_by_event_name`: Wait events summarized per event name
- `events_waits_summary_by_instance`: Wait events summarized per instance
- `events_waits_summary_by_thread_by_event_name`: Wait events summarized per thread and event name

File I/O Summaries:

- `file_summary_by_event_name`: File events summarized per event name
- `file_summary_by_instance`: File events summarized per file instance

The `events_waits_summary_global_by_event_name` table was named `EVENTS_WAITS_SUMMARY_BY_EVENT_NAME` before MySQL 5.5.7.

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with `TRUNCATE TABLE`. The effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change.

21.7.4.1. Event Wait Summary Tables

The event waits summary tables aggregate general information about event waits:

- `events_waits_summary_global_by_event_name`: Wait events summarized per event name
- `events_waits_summary_by_instance`: Wait events summarized per instance
- `events_waits_summary_by_thread_by_event_name`: Wait events summarized per thread and event name

For example:

```
mysql> SELECT * FROM events_waits_summary_global_by_event_name\G
...
***** 6. row *****
      EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
      COUNT_STAR: 8
      SUM_TIMER_WAIT: 2119302
      MIN_TIMER_WAIT: 196092
      AVG_TIMER_WAIT: 264912
      MAX_TIMER_WAIT: 569421
...
***** 9. row *****
      EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
      COUNT_STAR: 69
      SUM_TIMER_WAIT: 16848828
      MIN_TIMER_WAIT: 0
      AVG_TIMER_WAIT: 244185
      MAX_TIMER_WAIT: 735345
...
```

`TRUNCATE TABLE` is permitted for wait summary tables. It resets the counters to zero rather than removing rows.

The event wait summary tables have these grouping columns to indicate how events are aggregated:

- `events_waits_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given instrument. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.
- `events_waits_summary_by_instance` has `EVENT_NAME` and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given instrument instance. If an instrument is used to create multiple instances, each instance has a unique `OBJECT_INSTANCE_BEGIN` value, so these instances are summarized separately in this table.
- `events_waits_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and instrument.

The event waits summary tables have these summary columns containing aggregated values:

- `COUNT_STAR`

The number of summarized events. This value includes all events, whether timed or not.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of `NULL`. The same is true for the other `xxx_TIMER_WAIT` values.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed events.

21.7.4.2. File I/O Summary Tables

The file I/O summary tables aggregate information about I/O operations:

- `file_summary_by_event_name`: File events summarized per event name
- `file_summary_by_instance`: File events summarized per file instance

For example:

```
mysql> SELECT * FROM file_summary_by_instance\G
...
***** 2. row *****
      FILE_NAME: /var/mysql/share/english/errmsg.sys
      EVENT_NAME: wait/io/file/sql/ERRMSG
      COUNT_READ: 3
      COUNT_WRITE: 0
      SUM_NUMBER_OF_BYTES_READ: 42211
      SUM_NUMBER_OF_BYTES_WRITE: 0
...
***** 6. row *****
      FILE_NAME: /var/mysql/data/binlog.000001
      EVENT_NAME: wait/io/file/sql/binlog
      COUNT_READ: 0
      COUNT_WRITE: 0
      SUM_NUMBER_OF_BYTES_READ: 0
      SUM_NUMBER_OF_BYTES_WRITE: 0
...

```

`TRUNCATE TABLE` is permitted for file I/O summary tables. It resets the counters to zero rather than removing rows.

The file I/O summary tables have these grouping columns to indicate how events are aggregated:

- `file_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given instrument.
- `file_summary_by_instance` has `FILE_NAME` and `EVENT_NAME` columns. Each row summarizes events for a given file instrument instance.

The file I/O summary tables have these summary columns containing aggregated values:

- `COUNT_READ`

The number of read operations in the summarized events.

- [COUNT_WRITE](#)

The number of write operations in the summarized events.

- [SUM_NUMBER_OF_BYTES_READ](#)

The number of bytes read in the summarized events.

- [SUM_NUMBER_OF_BYTES_WRITE](#)

The number of bytes written in the summarized events.

The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events will not. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

21.7.5. Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

- [performance_timers](#): Which event timers are available.
- [threads](#): Information about server threads.

21.7.5.1. The [performance_timers](#) Table

The [performance_timers](#) table shows which event timers are available:

```
mysql> SELECT * FROM performance_timers;
```

| TIMER_NAME | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
|-------------|-----------------|------------------|----------------|
| CYCLE | 2389029850 | 1 | 72 |
| NANOSECOND | NULL | NULL | NULL |
| MICROSECOND | 1000000 | 1 | 585 |
| MILLISECOND | 1035 | 1 | 738 |
| TICK | 101 | 1 | 630 |

If the values associated with a given timer name are [NULL](#), that timer is not supported on your platform. The rows that do not contain [NULL](#) indicate which timers you can use in [setup_timers](#).

The [performance_timers](#) table has these columns:

- [TIMER_NAME](#)

The name by which to refer to the timer when configuring the [setup_timers](#) table.

- [TIMER_FREQUENCY](#)

The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the [CYCLE](#) may be close to 2400000000.

- [TIMER_RESOLUTION](#)

Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

- [TIMER_OVERHEAD](#)

The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

21.7.5.2. The `threads` Table

The `threads` table contains a row for each server thread:

```
mysql> SELECT * FROM threads;
+-----+-----+-----+
| THREAD_ID | PROCESSLIST_ID | NAME |
+-----+-----+-----+
| 0 | 0 | thread/sql/main |
| 1 | 0 | thread/innodb/io_handler_thread |
| 16 | 0 | thread/sql/signal_handler |
| 23 | 7 | thread/sql/one_connection |
| 5 | 0 | thread/innodb/io_handler_thread |
| 12 | 0 | thread/innodb/srv_lock_timeout_thread |
| 22 | 6 | thread/sql/one_connection |
| ... |
```

If you have the [PROCESS \[696\]](#) privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using).

The `threads` table has these columns:

- [THREAD_ID](#)

This is the unique identifier of an instrumented thread.

- [PROCESSLIST_ID](#)

For threads that are displayed in `INFORMATION_SCHEMA.PROCESSLIST`, this is the `INFORMATION_SCHEMA.ID` value, which is also the value that `CONNECTION_ID()` [1191] would return within that thread. For background threads (threads not associated with a user connection), `PROCESSLIST_ID` is 0, so the values are not unique.

This column was named `ID` before MySQL 5.5.8.

- [NAME](#)

`NAME` is the name associated with the instrumentation of the code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

The `threads` table was named `PROCESSLIST` before MySQL 5.5.6.

21.8. Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON |
```

Performance Schema System Variables

| | |
|---|---------|
| performance_schema_events_waits_history_long_size | 10000 |
| performance_schema_events_waits_history_size | 10 |
| performance_schema_max_cond_classes | 80 |
| performance_schema_max_cond_instances | 1000 |
| performance_schema_max_file_classes | 50 |
| performance_schema_max_file_handles | 32768 |
| performance_schema_max_file_instances | 10000 |
| performance_schema_max_mutex_classes | 200 |
| performance_schema_max_mutex_instances | 1000000 |
| performance_schema_max_rwlock_classes | 30 |
| performance_schema_max_rwlock_instances | 1000000 |
| performance_schema_max_table_handles | 100000 |
| performance_schema_max_table_instances | 50000 |
| performance_schema_max_thread_classes | 50 |
| performance_schema_max_thread_instances | 1000 |

Table 21.1. Performance Schema Variable Reference

| Name | Cmd-Line | Option file | System Var | Status Var | Var Scope | Dynamic |
|--|----------|-------------|------------|------------|-----------|---------|
| performance_schema_events_waits_history_long_size [2554] | Yes | Yes | Yes | | Global | No |
| Performance_schema_cond_classes_lost [2559] | | | | Yes | Global | No |
| Performance_schema_cond_instances_lost [2559] | | | | Yes | Global | No |
| performance_schema_events_waits_history_long_size [2554] | Yes | Yes | Yes | | Global | No |
| performance_schema_events_waits_history_size [2554] | Yes | Yes | Yes | | Global | No |
| Performance_schema_file_classes_lost [2559] | | | | Yes | Global | No |
| Performance_schema_file_handles_lost [2559] | | | | Yes | Global | No |
| Performance_schema_file_instances_lost [2559] | | | | Yes | Global | No |
| Performance_schema_locker_lost [2559] | | | | Yes | Global | No |
| performance_schema_max_cond_classes [2554] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_cond_instances [2554] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_file_classes [2555] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_file_handles [2555] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_file_instances [2556] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_mutex_classes [2557] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_mutex_instances [2558] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_rwlock_classes [2559] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_rwlock_instances [2559] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_table_handles [2557] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_table_instances [2558] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_thread_classes [2558] | Yes | Yes | Yes | | Global | No |
| performance_schema_max_thread_instances [2558] | Yes | Yes | Yes | | Global | No |
| Performance_schema_mutex_classes_lost [2559] | | | | Yes | Global | No |
| Performance_schema_mutex_instances_lost [2559] | | | | Yes | Global | No |
| Performance_schema_rwlock_classes_lost [2559] | | | | Yes | Global | No |
| Performance_schema_rwlock_instances_lost [2559] | | | | Yes | Global | No |
| Performance_schema_table_handles_lost [2559] | | | | Yes | Global | No |

| Name | Cmd-Line | Option file | System Var | Status Var | Var Scope | Dynamic |
|---|----------|-------------|------------|------------|-----------|---------|
| Performance_schema_table_instances_lost [2559] | | | | Yes | Global | No |
| Performance_schema_thread_classes_lost [2559] | | | | Yes | Global | No |
| Performance_schema_thread_instances_lost [2559] | | | | Yes | Global | No |

The variables have the following meanings:

- [performance_schema \[2554\]](#)

| | |
|-----------------------------|--|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema=#</code> |
| Option-File Format | <code>performance_schema=#</code> |
| Option Sets Variable | Yes, performance_schema [2554] |
| Variable Name | <code>performance_schema</code> |
| Variable Scope | Global |
| Dynamic Variable | No |

The value of this variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled. By default, the value is `OFF`. At server startup, you can specify this variable with no value or a value of 1 to enable it, or with a value of 0 to disable it.

- [performance_schema_events_waits_history_long_size \[2554\]](#)

| | |
|-----------------------------|--|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_events_waits_history_long_size=#</code> |
| Option-File Format | <code>performance_schema_events_waits_history_long_size=#</code> |
| Option Sets Variable | Yes, performance_schema_events_waits_history_long_size [2554] |
| Variable Name | <code>performance_schema_events_waits_history_long_size</code> |
| Variable Scope | Global |
| Dynamic Variable | No |

The number of rows in the `events_waits_history_long` table.

- [performance_schema_events_waits_history_size \[2554\]](#)

| | |
|-----------------------------|--|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_events_waits_history_size=#</code> |
| Option-File Format | <code>performance_schema_events_waits_history_size=#</code> |
| Option Sets Variable | Yes, performance_schema_events_waits_history_size [2554] |
| Variable Name | <code>performance_schema_events_waits_history_size</code> |
| Variable Scope | Global |
| Dynamic Variable | No |

The number of rows per thread in the `events_waits_history` table.

- [performance_schema_max_cond_classes \[2554\]](#)

| | | |
|-----------------------------|---|----------------------|
| Version Introduced | 5.5.3 | |
| Command-Line Format | <code>--performance_schema_max_cond_classes=#</code> | |
| Option-File Format | <code>performance_schema_max_cond_classes=#</code> | |
| Option Sets Variable | Yes, performance_schema_max_cond_classes [2554] | |
| Variable Name | <code>performance_schema_max_cond_classes</code> | |
| Variable Scope | Global | |
| Dynamic Variable | No | |
| | Permitted Values | |
| | Type | <code>numeric</code> |
| | Default | <code>80</code> |

The maximum number of condition instruments.

- [performance_schema_max_cond_instances \[2555\]](#)

| | | |
|-----------------------------|---|--|
| Version Introduced | 5.5.3 | |
| Command-Line Format | <code>--performance_schema_max_cond_instances=#</code> | |
| Option-File Format | <code>performance_schema_max_cond_instances=#</code> | |
| Option Sets Variable | Yes, performance_schema_max_cond_instances [2555] | |
| Variable Name | <code>performance_schema_max_cond_instances</code> | |
| Variable Scope | Global | |
| Dynamic Variable | No | |

The maximum number of instrumented condition objects.

- [performance_schema_max_file_classes \[2555\]](#)

| | | |
|-----------------------------|---|----------------------|
| Version Introduced | 5.5.3 | |
| Command-Line Format | <code>--performance_schema_max_file_classes=#</code> | |
| Option-File Format | <code>performance_schema_max_file_classes=#</code> | |
| Option Sets Variable | Yes, performance_schema_max_file_classes [2555] | |
| Variable Name | <code>performance_schema_max_file_classes</code> | |
| Variable Scope | Global | |
| Dynamic Variable | No | |
| | Permitted Values | |
| | Type | <code>numeric</code> |
| | Default | <code>50</code> |

The maximum number of file instruments.

- [performance_schema_max_file_handles \[2555\]](#)

| | | |
|----------------------------|--|--|
| Version Introduced | 5.5.3 | |
| Command-Line Format | <code>--performance_schema_max_file_handles=#</code> | |

| | | |
|-----------------------------|---|-------------------------|
| Option-File Format | <code>performance_schema_max_file_handles=#</code> | |
| Option Sets Variable | Yes, performance_schema_max_file_handles [2555] | |
| Variable Name | performance_schema_max_file_handles | |
| Variable Scope | Global | |
| Dynamic Variable | No | |
| | Permitted Values | |
| | Type | numeric |
| | Default | 32768 |

The maximum number of opened file objects.

The value of [performance_schema_max_file_handles \[2555\]](#) should be greater than the value of [open_files_limit \[535\]](#): [open_files_limit \[535\]](#) affects the maximum number of open file handles the server can support and [performance_schema_max_file_handles \[2555\]](#) affects how many of these file handles can be instrumented.

- [performance_schema_max_file_instances \[2556\]](#)

| | | |
|-----------------------------|---|--|
| Version Introduced | 5.5.3 | |
| Command-Line Format | <code>--performance_schema_max_file_instances=#</code> | |
| Option-File Format | <code>performance_schema_max_file_instances=#</code> | |
| Option Sets Variable | Yes, performance_schema_max_file_instances [2556] | |
| Variable Name | performance_schema_max_file_instances | |
| Variable Scope | Global | |
| Dynamic Variable | No | |

The maximum number of instrumented file objects.

- [performance_schema_max_mutex_classes \[2556\]](#)

| | | |
|-----------------------------|--|-------------------------|
| Version Introduced | 5.5.3 | |
| Command-Line Format | <code>--performance_schema_max_mutex_classes=#</code> | |
| Option-File Format | <code>performance_schema_max_mutex_classes=#</code> | |
| Option Sets Variable | Yes, performance_schema_max_mutex_classes [2556] | |
| Variable Name | performance_schema_max_mutex_classes | |
| Variable Scope | Global | |
| Dynamic Variable | No | |
| | Permitted Values | |
| | Type | numeric |
| | Default | 200 |

The maximum number of mutex instruments.

- [performance_schema_max_mutex_instances \[2556\]](#)

| | |
|---------------------------|-------|
| Version Introduced | 5.5.3 |
|---------------------------|-------|

| | |
|-----------------------------|--|
| Command-Line Format | <code>--performance_schema_max_mutex_instances=#</code> |
| Option-File Format | <code>performance_schema_max_mutex_instances=#</code> |
| Option Sets Variable | Yes, performance_schema_max_mutex_instances [2556] |
| Variable Name | <code>performance_schema_max_mutex_instances</code> |
| Variable Scope | Global |
| Dynamic Variable | No |

The maximum number of instrumented mutex objects.

- [performance_schema_max_rwlock_classes \[2557\]](#)

| | |
|-----------------------------|---|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_max_rwlock_classes=#</code> |
| Option-File Format | <code>performance_schema_max_rwlock_classes=#</code> |
| Option Sets Variable | Yes, performance_schema_max_rwlock_classes [2557] |
| Variable Name | <code>performance_schema_max_rwlock_classes</code> |
| Variable Scope | Global |
| Dynamic Variable | No |
| | Permitted Values |
| | Type <code>numeric</code> |
| | Default <code>20</code> |

The maximum number of rwlock instruments.

- [performance_schema_max_rwlock_instances \[2557\]](#)

| | |
|-----------------------------|---|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_max_rwlock_instances=#</code> |
| Option-File Format | <code>performance_schema_max_rwlock_instances=#</code> |
| Option Sets Variable | Yes, performance_schema_max_rwlock_instances [2557] |
| Variable Name | <code>performance_schema_max_rwlock_instances</code> |
| Variable Scope | Global |
| Dynamic Variable | No |

The maximum number of instrumented rwlock objects.

- [performance_schema_max_table_handles \[2557\]](#)

| | |
|-----------------------------|--|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_max_table_handles=#</code> |
| Option-File Format | <code>performance_schema_max_table_handles=#</code> |
| Option Sets Variable | Yes, performance_schema_max_table_handles [2557] |
| Variable Name | <code>performance_schema_max_table_handles</code> |
| Variable Scope | Global |

| | |
|-------------------------|----|
| Dynamic Variable | No |
|-------------------------|----|

The maximum number of opened table objects.

- [performance_schema_max_table_instances](#) [2558]

| | |
|-----------------------------|--|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_max_table_instances=#</code> |
| Option-File Format | <code>performance_schema_max_table_instances=#</code> |
| Option Sets Variable | Yes, performance_schema_max_table_instances [2558] |
| Variable Name | <code>performance_schema_max_table_instances</code> |
| Variable Scope | Global |
| Dynamic Variable | No |

The maximum number of instrumented table objects.

- [performance_schema_max_thread_classes](#) [2558]

| | |
|-----------------------------|---|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_max_thread_classes=#</code> |
| Option-File Format | <code>performance_schema_max_thread_classes=#</code> |
| Option Sets Variable | Yes, performance_schema_max_thread_classes [2558] |
| Variable Name | <code>performance_schema_max_thread_classes</code> |
| Variable Scope | Global |
| Dynamic Variable | No |
| | Permitted Values |
| | Type <code>numeric</code> |
| | Default <code>50</code> |

The maximum number of thread instruments.

- [performance_schema_max_thread_instances](#) [2558]

| | |
|-----------------------------|---|
| Version Introduced | 5.5.3 |
| Command-Line Format | <code>--performance_schema_max_thread_instances=#</code> |
| Option-File Format | <code>performance_schema_max_thread_instances=#</code> |
| Option Sets Variable | Yes, performance_schema_max_thread_instances [2558] |
| Variable Name | <code>performance_schema_max_thread_instances</code> |
| Variable Scope | Global |
| Dynamic Variable | No |

The maximum number of instrumented thread objects.

The [max_connections](#) [519] and [max_delayed_threads](#) [520] system variables affect how many threads are run in the server. [performance_schema_max_thread_instances](#) [2558] affects how many of these running threads can be instrumented. If you increase

`max_connections` [519] or `max_delayed_threads` [520], you should consider increasing `performance_schema_max_thread_instances` [2558] so that `performance_schema_max_thread_instances` [2558] is greater than the sum of `max_connections` [519] and `max_delayed_threads` [520].

21.9. Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```
mysql> SHOW STATUS LIKE 'perf%';
+-----+-----+
| Variable_name                | Value |
+-----+-----+
| Performance_schema_cond_classes_lost | 0     |
| Performance_schema_cond_instances_lost | 0     |
| Performance_schema_file_classes_lost  | 0     |
| Performance_schema_file_handles_lost  | 0     |
| Performance_schema_file_instances_lost | 0     |
| Performance_schema_locker_lost        | 0     |
| Performance_schema_mutex_classes_lost  | 0     |
| Performance_schema_mutex_instances_lost | 0     |
| Performance_schema_rwlock_classes_lost  | 0     |
| Performance_schema_rwlock_instances_lost | 0     |
| Performance_schema_table_handles_lost   | 0     |
| Performance_schema_table_instances_lost | 0     |
| Performance_schema_thread_classes_lost  | 0     |
| Performance_schema_thread_instances_lost | 0     |
+-----+-----+
```

Names for these variables have several forms:

- `Performance_schema_xxx_classes_lost`

How many instruments of type `xxx` could not be loaded.

- `Performance_schema_xxx_instances_lost`

How many instances of object type `xxx` could not be created.

- `Performance_schema_xxx_handles_lost`

How many instances of object type `xxx` could not be opened.

- `Performance_schema_locker_lost`

How many events are “lost” or not recorded, due to the following conditions:

- Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
- The depth of the nested events stack is greater than the limit imposed by the implementation.

Currently, events recorded by the Performance Schema are not recursive, so this variable should always be 0.

For information on using these variables to check Performance Schema status, see [Section 21.5, “Performance Schema Status Monitoring”](#).

21.10. Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin is unloaded later. The associated event information, including aggregate information, remains readable in `performance_schema` database tables. For additional information about the effect of plugin installation and removal, see [Section 21.5, “Performance Schema Status Monitoring”](#).

A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

21.11. Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in [Section 21.2.3.2, “Performance Schema Event Filtering”](#).

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.
2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis will rely heavily on post-filtering.
3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.
4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the `events_waits_history_long` table, will contain less and less “noise” caused by nonsignificant instruments, and given that this table has a fixed size, will contain more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the “signal/noise” ratio will improve, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:
 - Tune the server parameters (cache sizes, memory, and so forth).
 - Tune a query by writing it differently,
 - Tune the database schema (tables, indexes, and so forth).
 - Tune the code (this applies to storage engine or server developers only).
6. Start again at step 1, to see the effects of the changes on performance.

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:

1. Suppose that thread 1 is stuck waiting for a mutex.
2. You can determine what the thread is waiting for:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_1;
```

Say the query result identifies that the thread is waiting for mutex A, found in `events_waits_current.OBJECT_INSTANCE_BEGIN`.

3. You can determine which thread is holding mutex A:

```
SELECT * FROM mutex_instances WHERE OBJECT_INSTANCE_BEGIN = mutex_A;
```

Say the query result identifies that it is thread 2 holding mutex A, as found in `mutex_instances.LOCKED_BY_THREAD_ID`.

4. You can see what thread 2 is doing:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_2;
```

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including Java (JDBC), ODBC, Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

Note

Connector version numbers do not correlate with MySQL Server version numbers. See also [Table 22.2, “MySQL Connector Versions and MySQL Server Versions”](#).

A number of connectors are developed by MySQL:

- [Connector/ODBC](#) provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- [Connector/Net](#) enables developers to create .NET applications that use data stored in a MySQL database. Connector/Net implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/Net can be written in any of the supported .NET languages.

The MySQL Visual Studio Plugin works with Connector/Net and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools within Visual Studio to create and edit objects within a MySQL database.

- [Connector/J](#) provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- [Connector/Python](#) provides driver support for connecting to MySQL from a Python program using an API that is compliant with the [Python DB API version 2.0](#). No additional Python modules or MySQL client libraries are required.
- [Connector/C++](#) is a tool that enables easy deployment and management of MySQL server and database through your C++ application.
- [Connector/C](#) is a standalone replacement for the MySQL Client Library (`libmysql`).

There are two direct access methods for using MySQL natively within a C application:

- The C API provides low-level access to the MySQL protocol through the `libmysql` client library; this is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command line clients and many of the APIs also detailed in this section. MySQL Connector/C can now also be used for this purpose.
- `libmysqld` is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

If you need to access MySQL from a C application, or build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where you would start. A number of programmers utilities are available to help with the process, and also covered in this section.

The remaining APIs provide an interface to MySQL from specific application languages. These solutions are not developed or supported by MySQL. Basic information on their usage and abilities is provided here for reference purposes only.

All the language APIs are developed using one of two methods, using `libmysql` or by building a *native driver*. The two solutions offer different benefits:

- Using `libmysql` offers complete compatibility with MySQL as it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysql` and the performance may be lower as data is copied between the native language, and the MySQL API components. MySQL Connector/C is a possible alternative to using `libmysql`.
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier to build and deploy, as you do not need a copy of the MySQL client libraries to build the native driver components.

A list of many of the libraries and interfaces available for MySQL are shown in the table. See [Table 22.1, “MySQL APIs and Interfaces”](#).

Table 22.1. MySQL APIs and Interfaces

| Environment | API | Type | Notes |
|----------------|-------------------------------------|---------------------------------------|--|
| Ada | MySQL Bindings for GNU Ada | <code>libmysql</code> | See MySQL Bindings for GNU Ada |

Table 22.2. MySQL Connector Versions and MySQL Server Versions

| Connector | Connector version | MySQL Server version |
|----------------|------------------------------|---------------------------------|
| Connector/C++ | 1.0.5 GA | 5.6, 5.5, 5.4, 5.1 |
| Connector/J | 5.1.8 | 5.6, 5.5, 5.4, 5.1, 5.0, 4.1 |
| Connector/Net | 6.5 | 5.6, 5.5, 5.4, 5.1, 5.0 |
| Connector/Net | 6.4 | 5.6, 5.5, 5.4, 5.1, 5.0 |
| Connector/Net | 6.3 | 5.6, 5.5, 5.4, 5.1, 5.0 |
| Connector/Net | 6.2 (No longer supported) | 5.6, 5.5, 5.4, 5.1, 5.0 |
| Connector/Net | 6.1 (No longer supported) | 5.6, 5.5, 5.4, 5.1, 5.0 |
| Connector/Net | 6.0 (No longer supported) | 5.6, 5.5, 5.4, 5.1, 5.0 |
| Connector/Net | 5.2 (No longer supported) | 5.6, 5.5, 5.4, 5.1, 5.0 |
| Connector/Net | 1.0 (No longer supported) | 5.0, 4.0 |
| Connector/ODBC | 5.1 | 5.6, 5.5, 5.4, 5.1, 5.0, 4.1.1+ |
| Connector/ODBC | 3.51 (Unicode not supported) | 5.6, 5.5, 5.4, 5.1, 5.0, 4.1 |

22.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 5.2, which includes the functionality

Key connector/ODBC topics include:

of the Unicode driver and the ANSI driver, which formerly were split between Connector/ODBC 5.1 and Connector/ODBC 3.51.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, with full support for MySQL functionality, including stored procedures, [transactions](#) and, with Connector/ODBC 5.1 and higher, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to <http://support.microsoft.com/kb/110093>.

The application development section of the ODBC API reference assumes a good working knowledge of C, general DBMS, and a familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X, you can use the native MySQL network or named pipes to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

Key connector/ODBC topics include:

- Installing Connector/ODBC: [Section 22.1.3, “Connector/ODBC Installation”](#).
- The configuration options: [Section 22.1.4.2, “Connector/ODBC Connection Parameters”](#).
- An example that connects to a MySQL database from a Windows host: [Section 22.1.5.2, “Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC”](#).
- An example that uses Microsoft Access as an interface to a MySQL database: [Section 22.1.5.4, “Using Connector/ODBC with Microsoft Access”](#).
- General tips and notes, including how to obtain the last auto-increment ID: [Section 22.1.7.1, “Connector/ODBC General Functionality”](#).
- Application-specific usage tips and notes: [Section 22.1.7.2, “Connector/ODBC Application-Specific Tips”](#).
- A FAQ (Frequently Asked Questions) list: [Section 22.1.7.3, “Connector/ODBC Errors and Resolutions \(FAQ\)”](#).
- Additional Connector/ODBC support options: [Section 22.1.8, “Connector/ODBC Support”](#).

For release notes detailing the changes in each release of Connector/ODBC, see [MySQL Connector/ODBC Release Notes](#).

22.1.1. Connector/ODBC Versions

These are the versions of Connector/ODBC that are currently available:

- Connector/ODBC 5.2, currently in GA status, upgrades the ANSI driver of Connector/ODBC 3.51 to the 5.x code base. It also includes new features, such as enabling server-side prepared statements by default. At installation time, you can choose the Unicode driver for the broadest compatibility with data sources using various character sets, or the ANSI driver for optimal performance with a more limited range of character sets. It works with MySQL versions 4.1.1 and higher.
- Connector/ODBC 5.1, now superceded by 5.2, is a partial rewrite of the of the 3.51 code base, and is designed to work with MySQL versions 4.1.1 and newer.

Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

- Improved support on Windows 64-bit platforms.
- Full Unicode support at the driver level. This includes support for the `SQL_WCHAR` data type, and support for Unicode login, password and DSN configurations. For more information, see [Microsoft Knowledgebase Article #716246](#).
- Support for the `SQL_NUMERIC_STRUCT` data type, which provides easier access to the precise definition of numeric values. For more information, see [Microsoft Knowledgebase Article #714556](#)
- Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
- Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see [Microsoft Knowledgebase Article #716339](#).
- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) to continue to provide all functionality of ODBC for accessing MySQL.

With MySQL Connector/ODBC 5.2 now offering both ANSI and Unicode drivers, you should expect to upgrade relatively soon.

The manual for versions of Connector/ODBC older than 5.2 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

Note

From this section onward, the primary focus of this guide is the Connector/ODBC 5.2 driver.

Note

Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

22.1.2. Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that enables connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://support.microsoft.com/kb/110093>.

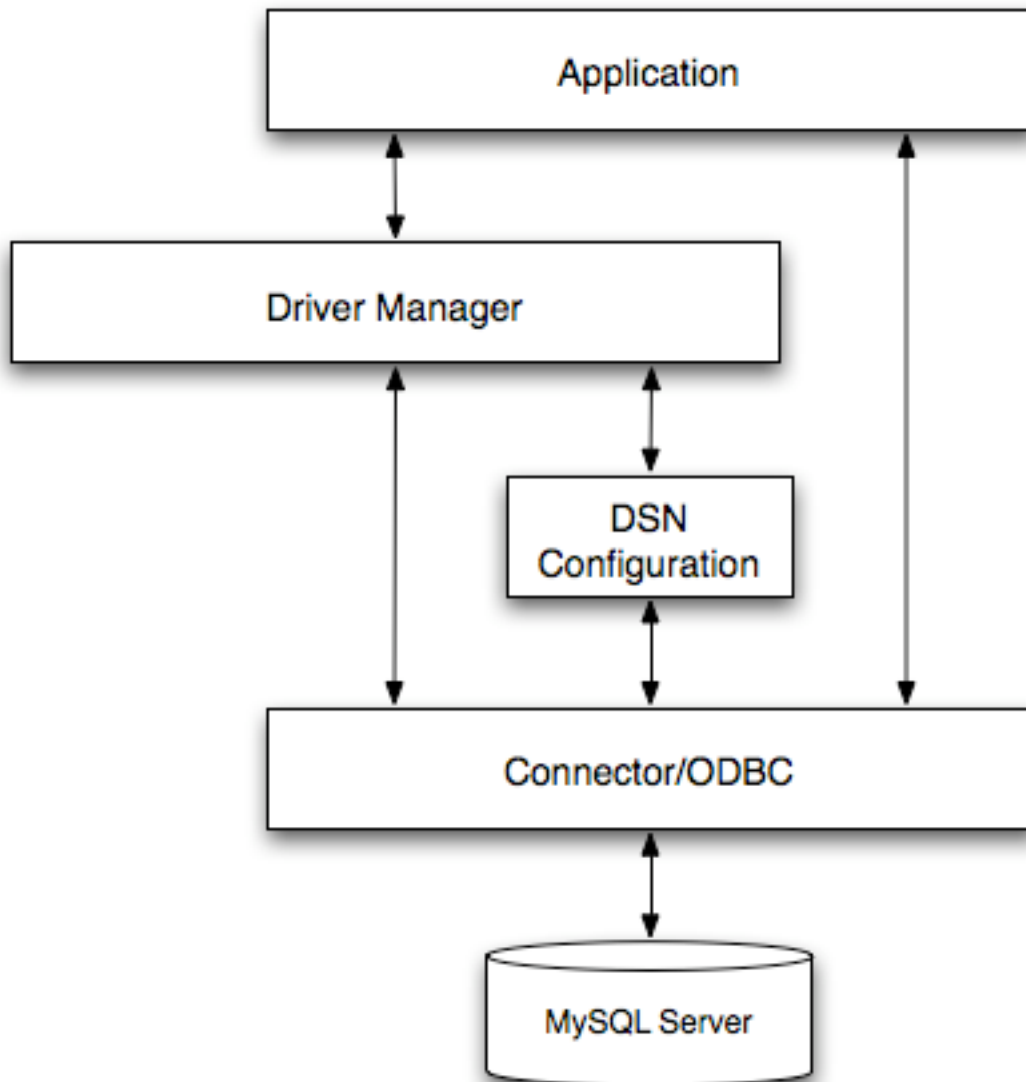

22.1.2.1. General Information About ODBC and Connector/ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at [Section 22.1.6.1, "Connector/ODBC API Reference"](#). For general information about ODBC, see <http://support.microsoft.com/kb/110093>.

22.1.2.1.1. Connector/ODBC Architecture

The Connector/ODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it.

- Submitting SQL statements for execution.
- Retrieving results (if any).
- Processing errors.
- [Committing](#) or [rolling back](#) the [transaction](#) enclosing the SQL statement.
- Disconnecting from the MySQL server.

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

- Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.
- Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, [Section 22.1.4, "Configuring Connector/ODBC"](#).

- **MySQL Server:**

The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

22.1.2.1.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers, are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://support.microsoft.com/kb/110093>.
- Mac OS X includes `ODBC Administrator`, a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. <http://www.apple.com>.
- `unixODBC` Driver Manager for Unix (`libodbc.so`). See <http://www.unixodbc.org>, for more information. The `unixODBC` Driver Manager includes the Connector/ODBC driver 3.51 in the installation package, starting with version `unixODBC 2.1.2`.
- `iODBC` ODBC Driver Manager for Unix (`libiodbc.so`), see <http://www.iodbc.org>, for more information.

22.1.3. Connector/ODBC Installation

This section explains where to download Connector/ODBC, and how to run the installer, copy the files manually, or build from source.

Where to Get Connector/ODBC

You can get a copy of the latest version of Connector/ODBC binaries and sources from our Web site at <http://dev.mysql.com/downloads/connector/odbc/>.

For more information about Connector/ODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

Choosing Unicode or ANSI Driver

Connector/ODBC offers the flexibility to handle data using any character set through its **Unicode-enabled** driver, or the maximum raw speed for a more limited range of character sets through its **ANSI** driver. Some users postponed their upgrade to Connector/ODBC 5.1, remaining with the older 3.51 version to keep this performance edge. As of Connector/ODBC 5.2, both kinds of drivers are available based on the 5.x code base: you can choose either a Unicode-enabled driver or an ANSI driver on the download page. The Unicode-enabled driver, recommended for most users, has no special qualifier in the download filename. The ANSI driver includes `-ansi-` in the download filename.

Note

You can install either the Unicode driver on a Windows system, or the ANSI driver, or both. The drivers are distinguished in the list of installed software and in the names of libraries and directories by a `w` (for “wide characters”) for the Unicode driver, and `a` in the ANSI driver.

Choosing Binary or Source Installation Method

You can install the Connector/ODBC drivers using two different methods:

- The **binary installation** is the easiest and most straightforward method of installation. You receive all the necessary libraries and other files pre-built, with an installer program or batch script to perform all necessary copying and configuration.
- The **source installation** method is intended for platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

If a binary distribution is not available for a particular platform, and you build the driver from the original source code, you can contribute the binaries you create to MySQL by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com), so that it becomes available for other users.

Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, 2003, Vista and 7.
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix.
- Mac OS X and Mac OS X Server.

Note

On all non-Windows platforms except Mac OS X, the driver is built against [unixODBC](#) and is expecting a 2-byte [SQLWCHAR](#), not 4 bytes as [iODBC](#) is using. For this reason, the binaries are **only** compatible with [unixODBC](#); recompile the driver against [iODBC](#) to use them together. For further information, see [Section 22.1.2.1.2, “ODBC Driver Managers”](#).

For further instructions, consult the documentation corresponding to the platform where you are installing and whether you are running a binary installer or building from source:

| Platform | Binary Installer | Build from Source |
|------------|---|------------------------------------|
| Windows | Installation Instructions | Build Instructions |
| Unix/Linux | Installation Instructions | Build Instructions |
| Mac OS X | Installation Instructions | |

22.1.3.1. Installing Connector/ODBC on Windows

Before installing the Connector/ODBC drivers on Windows, ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the [Microsoft Data Access and Storage](#) Web site.

There are different distribution types to use when installing for Windows. The software that is installed is identical in each case, only the installation method is different.

- The **zipped installer** consists of a zipped package containing a standalone installation application. To install from this package, unzip the installer, and then run the installation application.

The **MSI installer** is an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003.

See [Section 22.1.3.1.1, “Installing the Windows Connector/ODBC Driver Using an Installer”](#) for the steps to complete the installation with either of these installers.

- The **zipped DLL** package contains DLL files that must be manually installed. See [Section 22.1.3.1.2, “Installing the Windows Connector/ODBC Driver using the Zipped DLL Package”](#) for the steps to complete this type of installation.

Note

An OLEDB/ODBC driver for Windows 64-bit is available from [Microsoft Downloads](#).

22.1.3.1.1. Installing the Windows Connector/ODBC Driver Using an Installer

The zipped or MSI installer packages offer a very simple method for installing the Connector/ODBC drivers. If you have downloaded the zipped installer, extract the installer application. The basic installation process is identical for both installers.

Follow these steps to complete the installation:

1. Double-click the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC Setup Wizard starts. Click the **Next** button to begin the installation process.
3. Choose the installation type. The **Typical** installation provides the standard files needed to connect to a MySQL database using ODBC. The **Complete** option installs all the available files, including debug and utility components. Oracle recommends choosing one of these two options to complete the installation. If you choose one of these methods, click **Next**, then proceed to step 5.

You can also choose a **Custom** installation, where you select the individual components to install. If you choose this method, click **Next**, then proceed to step 4.

4. If you have chosen a custom installation, use the pop-ups to select which components to install, then click **Next** to install the necessary files.
5. Once the files are copied to their final locations, the installation is complete. Click **Finish** to exit the installer.

Now that the installation is complete, configure your ODBC connections using [Section 22.1.4, “Configuring Connector/ODBC”](#).

22.1.3.1.2. Installing the Windows Connector/ODBC Driver using the Zipped DLL Package

If you have downloaded the zipped DLL package:

1. Unzip the installation files.
2. Run the included batch file to perform an installation to the default locations.
3. Alternatively, install the individual files required for Connector/ODBC operation manually.

Note

The following instructions only work for 32-bit Windows systems. If you have a 64-bit Windows system, use the MSI installer, which installs both the 32-bit and 64-bit drivers to the correct locations.

To install using the **batch file**:

1. Unzip the Connector/ODBC zipped DLL package.
2. Open a command prompt.
3. Change to the directory created when you unzipped the Connector/ODBC zipped DLL package.
4. Run `Install.bat`:

```
C:\> Install.bat
```

This copies the necessary files into the default location, and then registers the Connector/ODBC driver with the Windows ODBC manager.

Note

Changing or adding a new DSN (data source name) may be accomplished using either the GUI, or from the command-line using `myodbc-installer.exe` with Connector/ODBC 5.x, or `myodbc3i.exe` with Connector/ODBC 3.51,

Although Oracle recommends installing these files in the standard location, you can also copy the files by hand to an alternative location - for example, to run or test different versions of the Connector/ODBC driver on the same machine. To **copy the files** to a location of your choice, use the following steps:

1. Unzip the Connector/ODBC zipped DLL package.
2. Open a command prompt.
3. Change to the directory created when you unzipped the Connector/ODBC zipped DLL package.
4. Copy the library files to a suitable directory. The default location is the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc5S.dll \Windows\System32
C:\> copy lib\myodbc5S.lib \Windows\System32

If installing the Unicode-enabled driver:
C:\> copy lib\myodbc5w.dll \Windows\System32
C:\> copy lib\myodbc5w.lib \Windows\System32

If installing the ANSI driver:
C:\> copy lib\myodbc5a.dll \Windows\System32
C:\> copy lib\myodbc5a.lib \Windows\System32
```

5. Copy the Connector/ODBC tools. These must be placed in a directory that is in the system `%PATH%`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally, copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc\*.hlp \Windows\System32
```

7. Finally, register the Connector/ODBC driver with the ODBC manager:

```
For Unicode-enabled driver:
C:\> myodbc3i -a -d -t"MySQL ODBC 5.2 Driver;\
```

```
DRIVER=myodbc5w.dll;SETUP=myodbc5S.dll"
```

For ANSI driver:

```
C:\> myodbc3i -a -d -t"MySQL ODBC 5.2 Driver;\
DRIVER=myodbc5a.dll;SETUP=myodbc5S.dll"
```

If you installed these files into a non-default location, change the references to the DLL files and command location in the above statement

22.1.3.2. Installing Connector/ODBC on Unix

There are two methods available for installing Connector/ODBC on Unix from a binary distribution. For most Unix environments, you will use the **tarball** distribution. For Linux systems, there is also an **RPM** distribution available.

Note

To install Connector/ODBC 5.x on Unix requires unixODBC 2.2.12 or later to be installed.

22.1.3.2.1. Installing Connector/ODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball, substituting the appropriate file and directory names based on the package you download:

```
shell> su root
shell> gunzip mysql-connector-odbc-5.2.2-i686-pc-linux.tar.gz
shell> tar xvf mysql-connector-odbc-5.2.2-i686-pc-linux.tar
shell> cd mysql-connector-odbc-5.2.2-i686-pc-linux
```

Read the installation instructions in the `INSTALL` file and execute these commands.

Then see [Section 22.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#) to configure the DSN for Connector/ODBC. For more information, refer to the `INSTALL` file that comes with your distribution.

22.1.3.2.2. Installing Connector/ODBC from an RPM Distribution

To install or upgrade Connector/ODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of Connector/ODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh mysql-connector-odbc-5.2.2.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh mysql-connector-odbc-5.2.2.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. See [Section 22.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#) for the post-installation configuration steps.

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e mysql-connector-odbc
```

22.1.3.3. Installing Connector/ODBC on Mac OS X

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the Connector/ODBC driver lets you connect to MySQL databases on any platform through the ODBC interface. If your application requires an ODBC interface, install the Connector/ODBC driver. Applications that require or can use ODBC (and therefore the Connector/ODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the `iODBC` manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying `iODBC` configuration files.

For Connector/ODBC 5.x, the package is provided as a compressed tar archive that you manually install.

In either case, the driver is designed to work with the `iODBC` driver manager included with Mac OS X.

To install Connector/ODBC 5.x:

1. Download the installation file for the appropriate level of OS X (10.5 or higher).
2. Extract the archive:

```
shell> tar xvzf mysql-connector-odbc-5.x.y-osx10.z-x86-(32/64)bit.tar.gz
```

3. The directory created contains the subdirectories, `lib`, `bin`, and `test`. Copy the contents of `lib` and `bin` to a suitable location such as `/usr/local`:

```
shell> sudo cp bin/* /usr/local/bin
shell> sudo cp lib/* /usr/local/lib
```

4. Finally, register the driver with `iODBC` using the `myodbc3i` tool you just installed:

```
shell> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;Driver=/usr/local/lib/libmyodbc3.so;Setup=/usr/local/li
```

To verify the installed drivers, either use the ODBC Administrator application or the `myodbc3i` utility:

```
shell> myodbc3i -q -d
```

22.1.3.4. Building Connector/ODBC from a Source Distribution on Windows

You only need to build Connector/ODBC from source on Windows to modify the source or installation location. If you are unsure whether to install from source, please use the binary installation detailed in [Section 22.1.3.1, "Installing Connector/ODBC on Windows"](#).

Building Connector/ODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from <http://support.microsoft.com/kb/110093>.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.

Microsoft Visual Studio 7 and 8 are preferred, and well-tested.

- Connector/ODBC 5.2: `cmake`.

- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

Build Steps

Set the environment variables for the Visual Studio toolchain. Visual Studio includes a batch file to set these for you, and installs a **Start** menu shortcut that opens a command prompt with these variables set.

Set `MYSQL_DIR` to the MySQL server installation path, while using the short-style file names. For example:

```
C:\> set MYSQL_DIR=C:\PROGRA~1\MySQL\MYSQLS~1.0
```

Build Connector/ODBC using the `cmake` command-line tool by executing the following from the source root directory (in a command prompt window):

```
C:\> cmake -G "Visual Studio 8 2005"
```

This produces a project file that you can open with Visual Studio, or build from the command line with either of the following commands:

```
C:\> devenv.com MySQL_Connector_ODBC.sln /build Release
C:\> devenv.com MySQL_Connector_ODBC.sln /build RelWithDebInfo
```

To compile a debug build, set the `cmake` build type so that the correct versions of the MySQL client libraries are used:

```
C:\> cmake -G "Visual Studio 8 2005" -DCMAKE_BUILD_TYPE=Debug
C:\> devenv.com MySQL_Connector_ODBC.sln /build Debug
```

Upon completion, the executables are in the `bin/` and `lib/` subdirectories.

See [Section 22.1.3.1.2, "Installing the Windows Connector/ODBC Driver using the Zipped DLL Package"](#) for the `copy` commands to complete the installation.

22.1.3.5. Building Connector/ODBC from a Source Distribution on Unix

Note

Connector/5.2 uses `cmake` for build, rather than `autoconf` and its `configure` command.

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. GCC 4.2.1 or later, Sun Studio 10 or later, Visual Studio 2008 or later, and many current vendor-supplied compilers are known to work.
- `cmake`.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

If you have built your own MySQL server or client libraries from source using the GNU autotools, use the `--enable-thread-safe-client` option to `configure` when the libraries were built. No special option is needed if you configure with `cmake`.

Also, ensure that the `libmysqlclient` library was built and installed as a shared library.

- A compatible ODBC manager must be installed. Connector/ODBC is known to work with the `iODBC` and `unixODBC` managers. See [Section 22.1.2.1.2, “ODBC Driver Managers”](#) for more information.
- If you are using a character set that is not compiled into the MySQL client library, install the MySQL character definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See [Section 10.1, “Character Set Support”](#) for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, then run `configure` and build the library using `make`.

Typical `cmake` Options

`iODBC` is the default ODBC library used by Connector/ODBC. Alternatively, `unixODBC` may be used by passing in the appropriate option to `cmake`. For example:

```
shell> cmake -G "Unix Makefiles" -DWITH_UNIXODBC=1
```

When you run `cmake`, you might add options to the command line. Here are some examples:

- `-DODBC_INCLUDES=dir_name [153]`: Used when the ODBC include directory is not found within the system `$PATH`.
- `-DODBC_LIB_DIR=dir_name [153]`: Used when the ODBC library directory is not found within the system `$PATH`.
- `-DWITH_UNIXODBC=1 [153]`: Enables `unixODBC` support.

Additional `configure` Options

There are a number of other options that you need, or want, to set when configuring the Connector/ODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so`. (The extensions are OS-dependent.)

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. Set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of Connector/ODBC using these options:

```
--enable-shared[=yes|no]
--disable-shared
--enable-static[=yes|no]
--disable-static
```

- By default, all the binary distributions are built as non-debug versions (configured with `--without-debug`).

To enable debugging information, build the driver from a source distribution with the proper configuration option to enable debugging support. See [Section 2.10.4, “MySQL Source-Configuration Options”](#).

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

Build Steps for Unix

To build the driver libraries, execute `make`:

```
shell> make
```

If any errors occur, correct them and continue the build process. If you are not able to build, then send a detailed email to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) for further assistance.

Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd mysql-connector-odbc-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error \
    -o .libs/libmyodbc3-3.51.01.so \
    catalog.o connect.o cursor.o dll.o error.o execute.o \
    handle.o info.o misc.o myodbc3.o options.o prepare.o \
    results.o transact.o utility.o \
    -L/usr/local/mysql/lib/mysql/ \
    -L/usr/local/iodbc/lib/ \
    -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the Connector/ODBC library installation directory (`/usr/local/lib`, or the `lib` directory under the installation directory that you supplied with the `--prefix` option).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
```

```
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \  
$CC -bundle -flat_namespace -undefined error  
-o .libs/libmyodbc3_r-3.51.01.so  
catalog.o connect.o cursor.o dll.o error.o execute.o  
handle.o info.o misc.o myodbc3.o options.o prepare.o  
results.o transact.o utility.o  
-L/usr/local/mysql/lib/mysql/  
-L/usr/local/iodbc/lib/  
-lz -lc -lmysqlclient_r -liodbcinst
```

Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For Connector/ODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe Connector/ODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For more information on build process, refer to the [INSTALL](#) file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

Testing Connector/ODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

22.1.3.6. Building Connector/ODBC from Source on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
```

```
--with-unixODBC=/usr/local
--with-mysql-path=/usr/local/mysql
--disable-shared
--enable-gui=no
--host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
    -L/usr/local/iodbc/lib
    -liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
    -L/usr/local/iodbc/lib
    -liodbcinst -lmysqlclient -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

22.1.3.7. Installing Connector/ODBC from the Development Source Tree

Caution

Read this section only if you are interested in helping us test our new code. To just get MySQL Connector/ODBC up and running on your system, use a standard release distribution.

To obtain the most recent development source tree, first download and install Bazaar from the [Bazaar VCS Web site](#). Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

Building from the source trees requires the following tools:

- `autoconf` 2.52 (or newer).
- `automake` 1.4 (or newer).
- `libtool` 1.4 (or newer).
- `m4`.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To check out the Connector/ODBC sources, change to the directory where you want the copy of the Connector/ODBC tree to be stored, then use the following command:

```
shell> bzip branch lp:myodbc
```

You should now have a copy of the entire Connector/ODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux, follow these steps:

```
shell> cd myodbc
shell> aclocal
shell> autoheader
shell> libtoolize -c -f
shell> autoconf
shell> automake;
shell> ./configure # Add your favorite options here
shell> make
```

When the build is done, run `make install` to install the Connector/ODBC driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to myodbc@lists.mysql.com.

On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver. For more information, see [Section 22.1.3.4, "Building Connector/ODBC from a Source Distribution on Windows"](#).

After the initial checkout operation to get the source tree, run `bzip pull` periodically to update your source according to the latest version.

22.1.4. Configuring Connector/ODBC

Before you connect to a MySQL database using the Connector/ODBC driver, you configure an ODBC Data Source Name (DSN). The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user-specific, system-specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

22.1.4.1. Overview of Connector/ODBC Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally, a DSN consists of the following parameters:

- Name
- Host Name
- Database Name
- Login
- Password

In addition, different ODBC drivers, including Connector/ODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

22.1.4.2. Connector/ODBC Connection Parameters

You can specify the parameters in the following tables for Connector/ODBC when configuring a DSN:

- [Table 22.3, “Connector/ODBC DSN Configuration Options”](#)
- [Table 22.4, “Connector/ODBC Option Flags”](#)

Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and check boxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

Table 22.3. Connector/ODBC DSN Configuration Options

| Parameter | Default Value | Comment |
|---|------------------------|--|
| <code>user</code> | ODBC | The user name used to connect to MySQL. |
| <code>uid</code> | ODBC | Synonymous with <code>user</code> . Added in 3.51.16. |
| <code>server</code> | <code>localhost</code> | The host name of the MySQL server. |
| <code>database</code> | | The default database. |
| <code>option</code> | 0 | Options that specify how Connector/ODBC works. See Table 22.4, “Connector/ODBC Option Flags” and Table 22.5, “Recommended Connector/ODBC option Values for Different Configurations” . |
| <code>port</code> | 3306 | The TCP/IP port to use if <code>server</code> is not <code>localhost</code> . |
| <code>initstmt</code> | | Initial statement. A statement to execute when connecting to MySQL. In version 3.51 the parameter is called <code>stmt</code> . Note, the driver supports the initial statement being executed only at the time of the initial connection. |
| <code>password</code> | | The password for the <code>user</code> account on <code>server</code> . |
| <code>pwd</code> | | Synonymous with <code>password</code> . Added in 3.51.16. |
| <code>socket</code> [553] | | The Unix socket file or Windows named pipe to connect to if <code>server</code> is <code>localhost</code> . |
| <code>sslca</code> | | The path to a file with a list of trust SSL CAs. Added in 3.51.16. |
| <code>sslcapath</code> | | The path to a directory that contains trusted SSL CA certificates in PEM format. Added in 3.51.16. |
| <code>sslcert</code> | | The name of the SSL certificate file to use for establishing a secure connection. Added in 3.51.16. |

| Parameter | Default Value | Comment |
|---------------------------|---------------|---|
| <code>sslcipher</code> | | A list of permissible ciphers to use for SSL encryption. The cipher list has the same format as the <code>openssl ciphers</code> command. Added in 3.51.16. |
| <code>sslkey</code> | | The name of the SSL key file to use for establishing a secure connection. Added in 3.51.16. |
| <code>charset</code> | | The character set to use for the connection. Added in 3.51.17. |
| <code>sslverify</code> | | If set to 1, the SSL certificate will be verified when used with the MySQL connection. If not set, then the default behavior is to ignore SSL certificate verification. |
| <code>readtimeout</code> | | The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP <code>Close_Wait_Timeout</code> value of 10 minutes. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_READ_TIMEOUT</code> option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27. |
| <code>writetimeout</code> | | The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are <code>net_retry_count</code> retries if necessary, so the total effective timeout value is <code>net_retry_count</code> times the option value. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the <code>MYSQL_OPT_WRITE_TIMEOUT</code> option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27. |
| <code>interactive</code> | | Enables the <code>CLIENT_INTERACTIVE</code> connection option of <code>mysql_real_connect</code> . |
| <code>prefetch</code> | 0 | When set to a non-zero value <i>N</i> , causes all queries in the connection to return <i>N</i> rows at a time rather than the entire result set. Useful for queries against very large tables where it is not practical to retrieve the whole result set at once. You can scroll through the result set, <i>N</i> records at a time. This option works only with forward-only cursors. It does not work when the <code>FLAG_MULTI_STATEMENTS</code> flag is set. It can be used in combination with the <code>FLAG_NO_CACHE</code> option. Its behavior in ADO applications is undefined: the prefetching might or might not occur. |
| <code>no_ssps</code> | 0 | In Connector/ODBC 5.2, by default, server-side prepared statements are used. When this option is set to a non-zero value, prepared statements are emulated on the client side, which is the same behavior as in 5.1 and 3.51. Added in 5.2. |

Note

The SSL configuration parameters can also be automatically loaded from a `my.ini` or `my.cnf` file. See [Section 4.2.3.3, “Using Option Files”](#).

The `option` argument is used to tell Connector/ODBC that the client is not 100% ODBC-compliant. On Windows, you normally select options by toggling the check boxes in the connection screen, but you can

also select them in the `option` argument. The following options are listed in the order in which they appear in the Connector/ODBC connect screen.

Table 22.4. Connector/ODBC Option Flags

| Flag Name | GUI Option | Constant Value | Description |
|-------------------------------------|---------------------------------------|----------------|--|
| <code>FLAG_FIELD_LENGTH</code> | Do not Optimize Column Width | | The client cannot handle that Connector/ODBC returns the real width of a column. This option was removed in 3.51.18. |
| <code>FLAG_FOUND_ROWS</code> | Return Matching Rows | 2 | The client cannot handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns “found rows” instead. You must have MySQL 3.21.14 or newer for this to work. |
| <code>FLAG_DEBUG</code> | Trace Driver Calls To myodbc.log | | Make a debug log in <code>C:\myodbc.log</code> on Windows, or <code>/tmp/myodbc.log</code> on Unix variants. This option was removed in Connector/ODBC 3.51.18. |
| <code>FLAG_BIG_PACKETS</code> | Allow Big Results | 8 | Do not set any packet limit for results and bind parameters. Without this option, parameter binding will be truncated to 255 characters. |
| <code>FLAG_NO_PROMPT</code> | Do not Prompt Upon Connect | 16 | Do not prompt for questions even if driver would like to prompt. |
| <code>FLAG_DYNAMIC_CURSOR</code> | Enable Dynamic Cursor | 32 | Enable or disable the dynamic cursor support. |
| <code>FLAG_NO_SCHEMA</code> | Ignore # in Table Name | 64 | Ignore use of database name in <code>db_name.tbl_name.col_name</code> . |
| <code>FLAG_NO_DEFAULT_CURSOR</code> | User Manager Cursors | 128 | Force use of ODBC manager cursors (experimental). |
| <code>FLAG_NO_LOCALE</code> | Do not Use Set Locale | 256 | Disable the use of extended fetch (experimental). |
| <code>FLAG_PAD_SPACE</code> | Pad Char To Full Length | 512 | Pad <code>CHAR</code> columns to full column length. |
| <code>FLAG_FULL_COLUMN_NAMES</code> | Return Table Names for SQLDescribeCol | 1024 | <code>SQLDescribeCol()</code> returns fully qualified column names. |
| <code>FLAG_COMPRESSED_PROTO</code> | Use Compressed Protocol | 2048 | Use the compressed client/server protocol. |
| <code>FLAG_IGNORE_SPACE</code> | Ignore Space After Function Names | 4096 | Tell server to ignore space after function name and before “(” (needed by PowerBuilder). This makes all function names keywords. |

Configuring Connector/ODBC

| Flag Name | GUI Option | Constant Value | Description |
|----------------------|--|----------------|---|
| FLAG_NAMED_PIPE | Force Use of Named Pipes | 8192 | Connect with named pipes to a <code>mysqld</code> server running on NT. |
| FLAG_NO_BIGINT | Change BIGINT Columns to Int | 16384 | Change <code>BIGINT</code> columns to <code>INT</code> columns (some applications cannot handle <code>BIGINT</code>). |
| FLAG_NO_CATALOG | No Catalog | 32768 | Forces results from the catalog functions, such as <code>SQLTables</code> , to always return <code>NULL</code> and the driver to report that catalogs are not supported. |
| FLAG_USE_MYCNF | Read Options From <code>my.cnf</code> | 65536 | Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> . |
| FLAG_SAFE | Safe | 131072 | Add some extra safety checks. |
| FLAG_NO_TRANSACTIONS | Disable <code>transactions</code> | 262144 | Disable transactions. |
| FLAG_LOG_QUERY | Save queries to <code>myodbc.sql</code> | 524288 | Enable query logging to <code>c:\myodbc.sql(/tmp/myodbc.sql)</code> file. (Enabled only in debug mode.) |
| FLAG_NO_CACHE | Do not Cache Result (forward only cursors) | 1048576 | Do not cache the results locally in the driver, instead read from server (<code>mysql_use_result()</code>). This works only for forward-only cursors. This option is very important in dealing with large tables when you do not want the driver to cache the entire result set. |
| FLAG_FORWARD_CURSOR | Force Use Of Forward Only Cursors | 2097152 | Force the use of <code>Forward-only</code> cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use noncache result sets, then this option ensures the forward-only cursor behavior. |
| FLAG_AUTO_RECONNECT | Enable auto-reconnect. | 4194304 | Enables auto-reconnection functionality. Do not use this option with <code>transactions</code> , since an auto-reconnection during a incomplete transaction may cause corruption. Note that an auto-reconnected connection will not inherit the same settings and environment as the original. This option was added in Connector/ODBC 3.51.13. |

| Flag Name | GUI Option | Constant Value | Description |
|---------------------------------------|------------------------------------|----------------|---|
| FLAG_AUTO_IS_NULL | Flag Auto Is Null | 8388608 | <p>When FLAG_AUTO_IS_NULL is set, the driver does not change the default value of sql_auto_is_null [554], leaving it at 1, so you get the MySQL default, not the SQL standard behavior.</p> <p>When FLAG_AUTO_IS_NULL is not set, the driver changes the default value of SQL_AUTO_IS_NULL to 0 after connecting, so you get the SQL standard, not the MySQL default behavior.</p> <p>Thus, omitting the flag disables the compatibility option and forces SQL standard behavior.</p> <p>See IS NULL [1091]. This option was added in Connector/ODBC 3.51.13.</p> |
| FLAG_ZERO_DATE_TO_MIN | Return SQL_NULL_DATA for zero date | 16777216 | <p>Translates zero dates (xxxx-00-00) into the minimum date values supported by ODBC, xxxx-01-01. This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.</p> |
| FLAG_MIN_DATE_TO_ZERO | Bind minimal date as zero date | 33554432 | <p>Translates the minimum ODBC date value (xxxx-01-01) to the zero date format supported by MySQL (xxxx-00-00). This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.</p> |
| FLAG_MULTI_STATEMENTS | Allow multiple statements | 67108864 | <p>Enables support for batched statements. This option was added in Connector/ODBC 3.51.18.</p> |
| FLAG_COLUMN_SIZE_S32 | Limit column size to 32-bit value | 134217728 | <p>Limits the column size to a signed 32-bit value to prevent</p> |

| Flag Name | GUI Option | Constant Value | Description |
|---|---|----------------|--|
| | | | problems with larger column sizes in applications that do not support them. This option is automatically enabled when working with ADO applications. This option was added in Connector/ODBC 3.51.22. |
| <code>FLAG_NO_BINARY_RESULT</code> | Always handle binary function results as character data | 268435456 | When set this option disables charset 63 for columns with an empty <code>org_table</code> . This option was added in Connector/ODBC 3.51.26. |
| <code>FLAG_DFLT_BIGINT_BIND_STR</code> | | 536870912 | Causes <code>BIGINT</code> parameters to be bound as strings. Microsoft Access treats <code>BIGINT</code> as a string on linked tables. The value is read correctly, but bound as a string. This option is used automatically if the driver is used by Microsoft Access. |
| <code>FLAG_NO_INFORMATION_SCHEMA</code> | | 1073741824 | Tells catalog functions not to use <code>INFORMATION_SCHEMA</code> , but rather use legacy algorithms. The trade-off here is usually speed for information quality. Using <code>INFORMATION_SCHEMA</code> is often slow, but the information obtained is more complete. |

To select multiple options, add together their values, using the numbers from the `Constant Value` column in the table.

Note

In MySQL Connector/ODBC 5.2, you can use the flag name directly as a parameter in the connection string, by specifying the flag name without the `FLAG_` prefix. So, in addition to using the `options` parameter with various flags set, you can use the flags directly as parameters. For example, `FIELD_LENGTH`, `FOUND_ROWS` and `DEBUG` could all be used as parameters.

The following table shows some recommended `option` values for various configurations:

Table 22.5. Recommended Connector/ODBC option Values for Different Configurations

| Configuration | Option Value |
|---|--------------|
| Microsoft Access, Visual Basic | 3 |
| Driver trace generation (Debug mode) | 4 |
| Microsoft Access (with improved DELETE queries) | 35 |
| Large tables with too many rows | 2049 |

| Configuration | Option Value |
|---|--------------|
| Sybase PowerBuilder | 135168 |
| Query log generation (Debug mode) | 524288 |
| Generate driver trace as well as query log (Debug mode) | 524292 |
| Large tables with no-cache results | 3145731 |

22.1.4.3. Configuring a Connector/ODBC DSN on Windows

The [ODBC Data Source Administrator](#) within Windows lets you create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the [ODBC Data Source Administrator](#) in different locations depending on the version of Windows that you are using.

To open the [ODBC Data Source Administrator](#) in Windows Server 2003:

Tip

To identify whether a DSN was created using the 32-bit or the 64-bit driver, include the driver being used within the DSN identifier. This will help you to identify the right DSN to use with applications such as Excel that are only compatible with the 32-bit driver. For example, you might add [Using32bitCOBDC](#) to the DSN identifier for the 32-bit interface and [Using64bitCOBDC](#) for those using the 64-bit Connector/ODBC driver.

1. On the [Start](#) menu, choose [Administrative Tools](#), and then click [Data Sources \(ODBC\)](#).

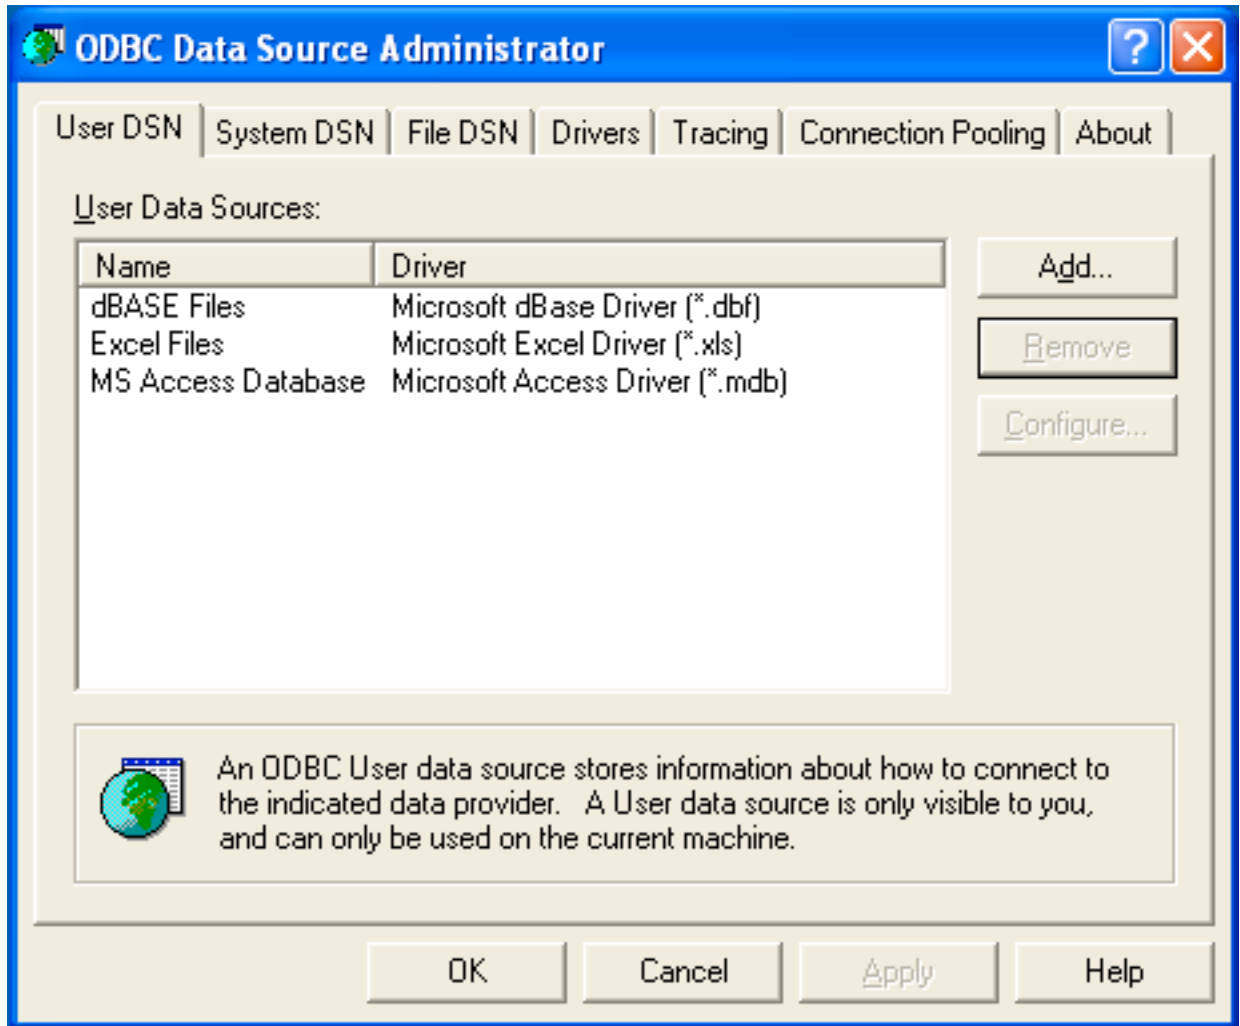

To open the [ODBC Data Source Administrator](#) in Windows 2000 Server or Windows 2000 Professional:

1. On the [Start](#) menu, choose [Settings](#), and then click [Control Panel](#).
2. In [Control Panel](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

To open the [ODBC Data Source Administrator](#) on Windows XP:

1. On the [Start](#) menu, click [Control Panel](#).
2. In the [Control Panel](#) when in [Category View](#) click [Performance and Maintenance](#) and then click [Administrative Tools](#).. If you are viewing the [Control Panel](#) in [Classic View](#), click [Administrative Tools](#).
3. In [Administrative Tools](#), click [Data Sources \(ODBC\)](#).

Irrespective of your Windows version, you should be presented the [ODBC Data Source Administrator](#) window:

Within Windows XP, you can add the [Administrative Tools](#) folder to your **Start** menu to make it easier to locate the ODBC Data Source Administrator. To do this:

1. Right-click the **Start** menu.
2. Select [Properties](#).
3. Click [Customize...](#)
4. Select the [Advanced](#) tab.
5. Within [Start menu items](#), within the [System Administrative Tools](#) section, select [Display on the All Programs menu](#).

Within both Windows Server 2003 and Windows XP, consider permanently adding the [ODBC Data Source Administrator](#) to your **Start** menu. To do this, locate the [Data Sources \(ODBC\)](#) icon using the methods shown, then right-click on the icon and then choose [Pin to Start Menu](#).

The interfaces for the 3.51 and 5.x versions of the Connector/ODBC driver are different, although the fields and information that you need to enter remain the same.

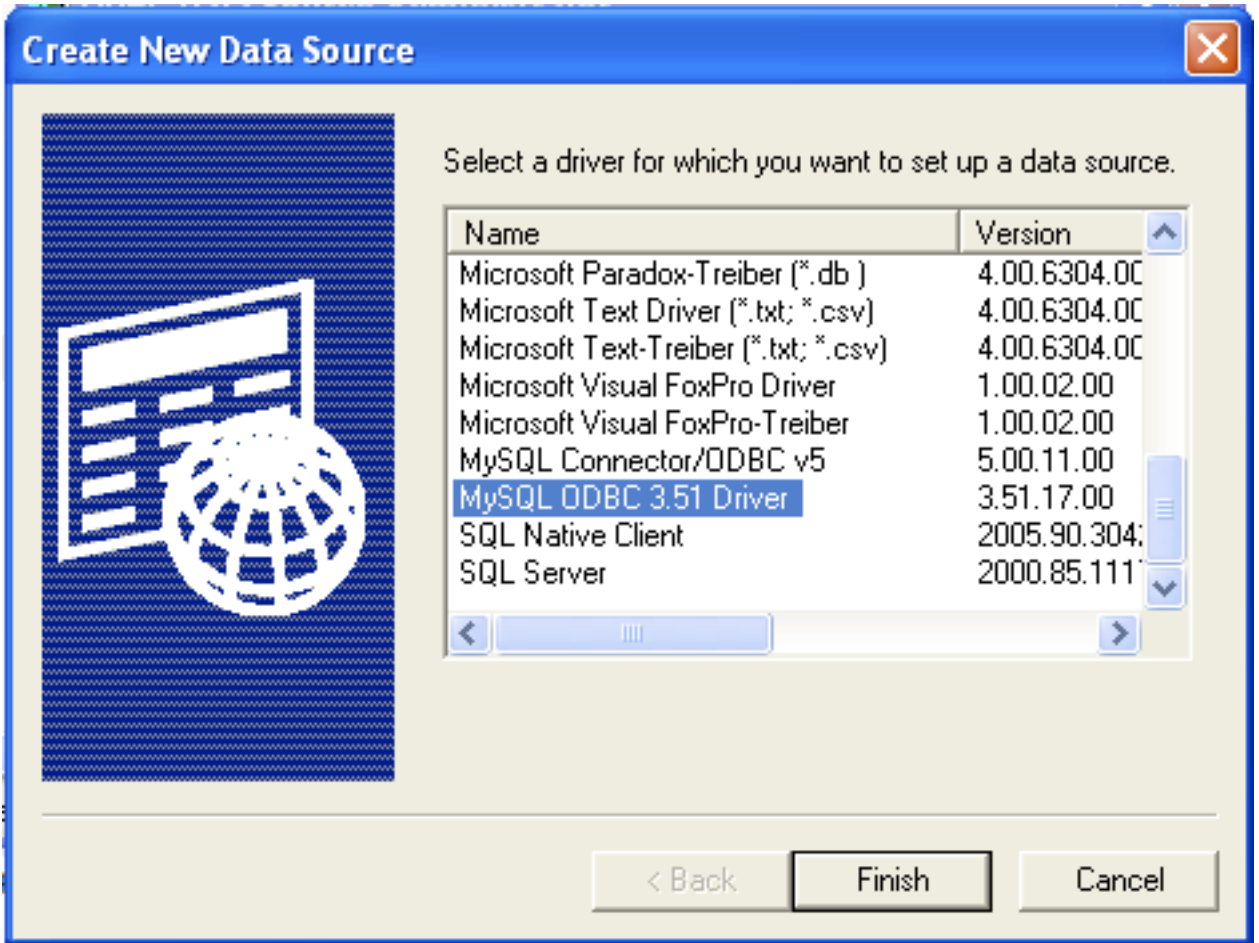

To configure a DSN using Connector/ODBC 5.2, see [Section 22.1.4.3.1, "Configuring a Connector/ODBC 5.x DSN on Windows"](#).

22.1.4.3.1. Configuring a Connector/ODBC 5.x DSN on Windows

Due to the native Unicode support within Connector/ODBC, you do not need to specify the initial character set to be used with your connection.

To add or configure a Connector/ODBC 5.x DSN on Windows, use either the command-line, or the [ODBC Data Source Administrator](#) GUI.

1. Open the [ODBC Data Source Administrator](#).
2. To create a System DSN (which will be available to all users), select the **System DSN** tab. To create a User DSN, which will be unique only to the current user, click the **Add...** button.
3. Select the ODBC driver for this DSN.

Select [MySQL ODBC 5.x Driver](#) for the appropriate level of Connector/ODBC, then click **Finish**.

4. You now need to configure the specific fields for the DSN you are creating through the [Connection Parameters](#) dialog.

MySQL Connector/ODBC Data Source Configuration

MySQL Connector/ODBC

Connection Parameters

Data Source Name:

Description:

Server: Port:

User:

Password:

Database:

In the **Data Source Name** box, enter the name of the data source to access. It can be any valid name that you choose.

5. In the **Description** box, enter some text to help identify the connection.
6. In the **Server** field, enter the name of the MySQL server host to access. By default, it is `localhost`.
7. In the **User** field, enter the user name to use for this connection.
8. In the **Password** field, enter the corresponding password for this connection.
9. The **Database** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. To communicate over a different TCP/IP port than the default (3306), change the value of the **Port**.
11. Click **OK** to save the DSN.

To verify the connection using the parameters you have entered, click the **Test** button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

You can configure a number of options for a specific DSN by using the **Details** button.

MySQL Connector/ODBC Data Source Configuration

MySQL Connector/ODBC

Connection Parameters

Data Source Name:

Description:

Server: Port:

User:

Password:

Database:

Flags 1 | Flags 2 | Flags 3 | Debug | SSL Settings

Return matched rows instead of affected rows

Allow big result sets

Use compression

Treat BIGINT columns as INT columns

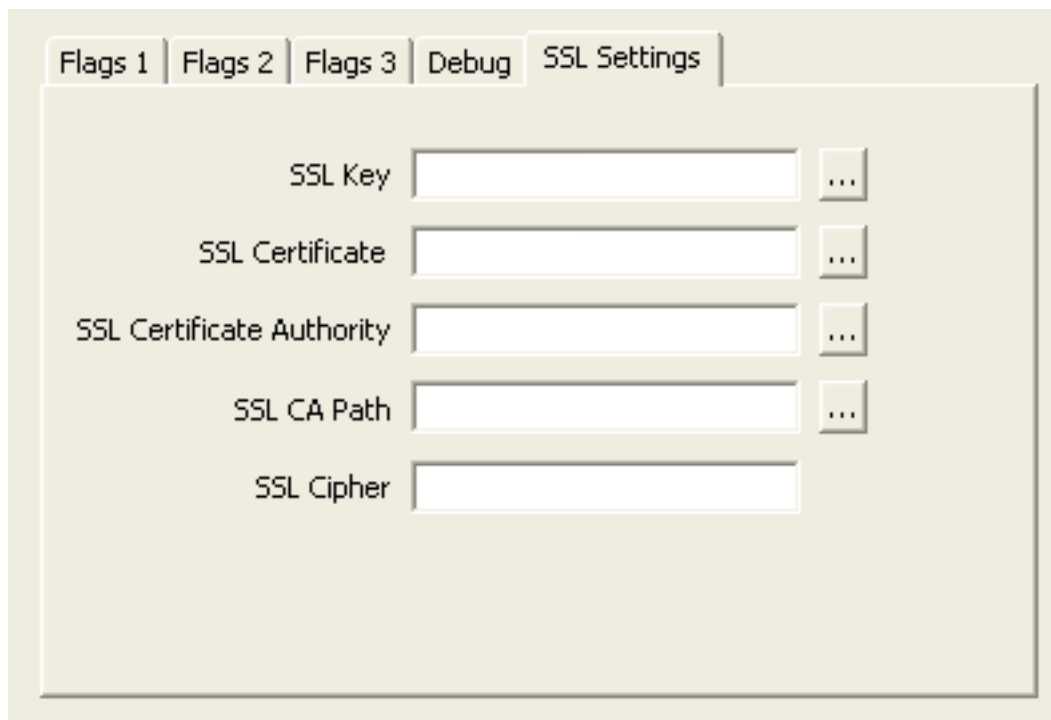

Enable safe options (see documentation)

Enable automatic reconnect

Enable SQL_AUTO_IS_NULL

The **Details** button opens a tabbed display where you set additional options:

- **Flags 1**, **Flags 2**, and **Flags 3** enable you to select the additional flags for the DSN connection. For more information on these flags, see [Section 22.1.4.2, “Connector/ODBC Connection Parameters”](#).
- **Debug** lets you turn on ODBC debugging to record the queries you execute through the DSN to the `myodbc.sql` file. For more information, see [Section 22.1.4.8, “Getting an ODBC Trace File”](#).
- **SSL Settings** configures the additional options required for using the Secure Sockets Layer (SSL) when communicating with MySQL server. Note that you must also enable SSL and configure the MySQL server with suitable certificates to communicate over SSL.

The Advanced tab lets you configure Connector/ODBC connection parameters. Refer to [Section 22.1.4.2, “Connector/ODBC Connection Parameters”](#), for information about the meaning of these options.

22.1.4.3.2. Configuring a Connector/ODBC 5.x DSN on Windows, Using the Command Line

Use `myodbc-installer.exe` when configuring Connector/ODBC 5.1 or later from the command-line.

Execute `myodbc-installer.exe` without arguments to view a list of available options.

22.1.4.3.3. Troubleshooting ODBC Connection Problems

This section answers Connector/ODBC connection-related questions.

- **While configuring a Connector/ODBC DSN, a `Could Not Load Translator or Setup Library` error occurs**

For more information, refer to [MS KnowledgeBase Article\(Q260558\)](#). Also, make sure you have the latest valid `ct13d32.dll` in your system directory.

- On Windows, the default `myodbc5w.dll` (Unicode) or `myodbc5a.dll` (ANSI) is compiled for optimal performance. To debug Connector/ODBC (for example, to enable tracing), instead use `myodbc5d.dll`.

To install this file, copy `myodbc5d.dll` over the installed `myodbc5w.dll` or `myodbc5a.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging, because the debug version may cause performance issues.

22.1.4.4. Configuring a Connector/ODBC DSN on Mac OS X

To configure a DSN on Mac OS X, you can either use the command-line utility (`myodbc-installer` with connector/ODBC 5.1, or `myodbc3i` with connector/OCBC 3.51), edit the `odbc.ini` file within the `Library/ODBC` directory of the user, or use the ODBC Administrator GUI. If you have Mac OS X 10.2 or earlier, refer to [Section 22.1.4.5, “Configuring a Connector/ODBC DSN on Unix”](#). Select whether to create a User DSN or a System DSN. When adding a System DSN, you might need to authenticate with the system. Click the padlock and enter a user and password with administrator privileges.

For correct operation of ODBC Administrator, ensure that the `/Library/ODBC/odbc.ini` file used to set up ODBC connectivity and DSNs are writable by the `admin` group. If this file is not writable by this group, then the ODBC Administrator may fail, or may appear to work but not generate the correct entry.

Warning

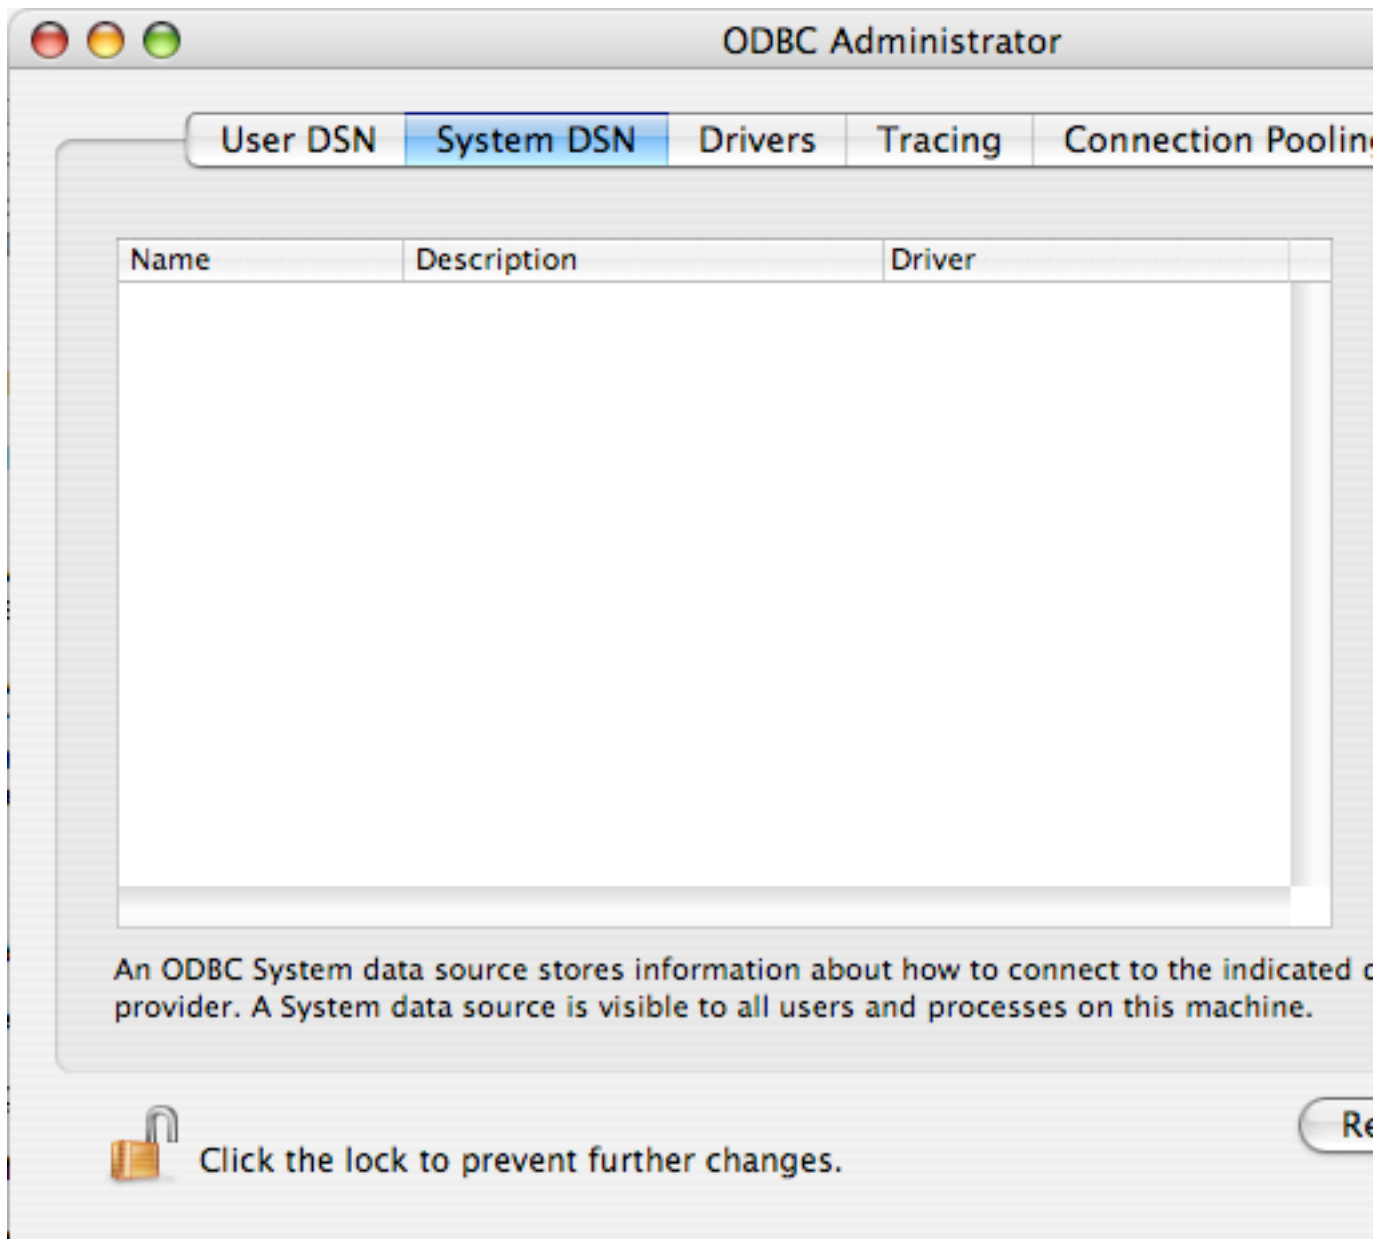

There are known issues with the OS X ODBC Administrator and Connector/ODBC that may prevent you from creating a DSN using this method. In this case, use the command line or edit the `odbc.ini` file directly. Note that existing DSNs or those that you create using the `myodbc3i` or `myodbc-installer` tool can still be checked and edited using ODBC Administrator.

To create a DSN using the `myodbc3i` utility, you need only specify the DSN type and the DSN connection string. For example:

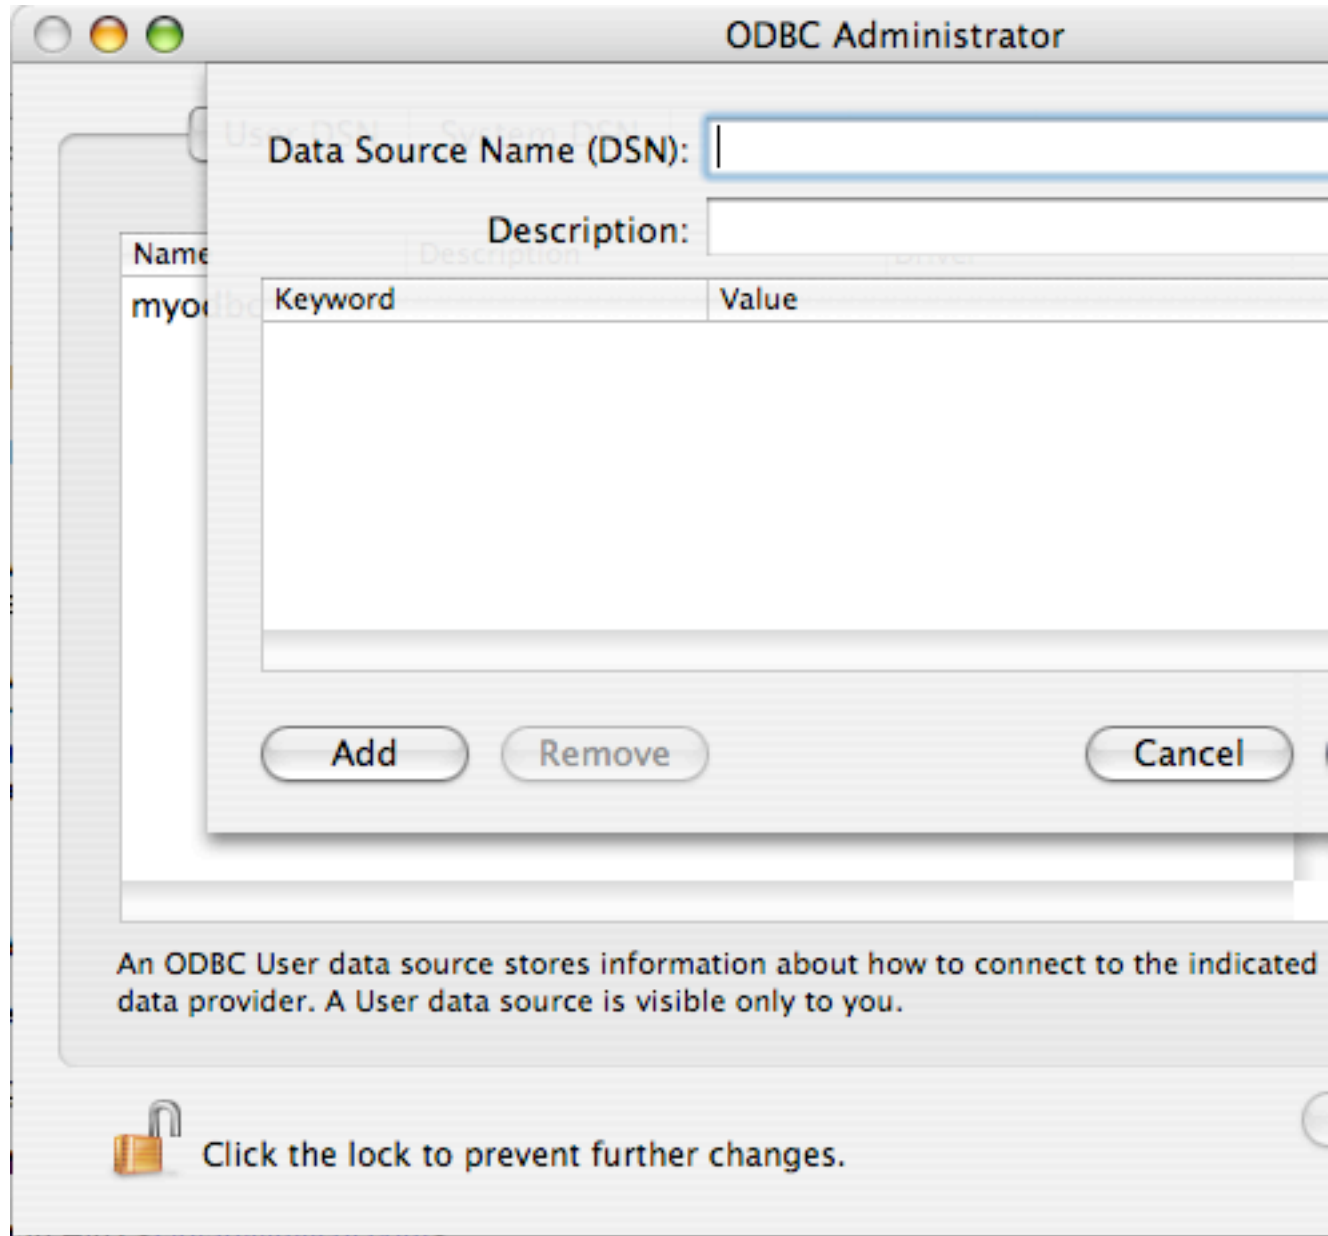

```
shell> myodbc3i -a -s -t "DSN=mydb;DRIVER=MySQL ODBC 3.51 Driver;SERVER=mysql;USER=username;PASSWORD=pass"
```

To use ODBC Administrator:

1. Open the ODBC Administrator from the `Utilities` folder in the `Applications` folder.

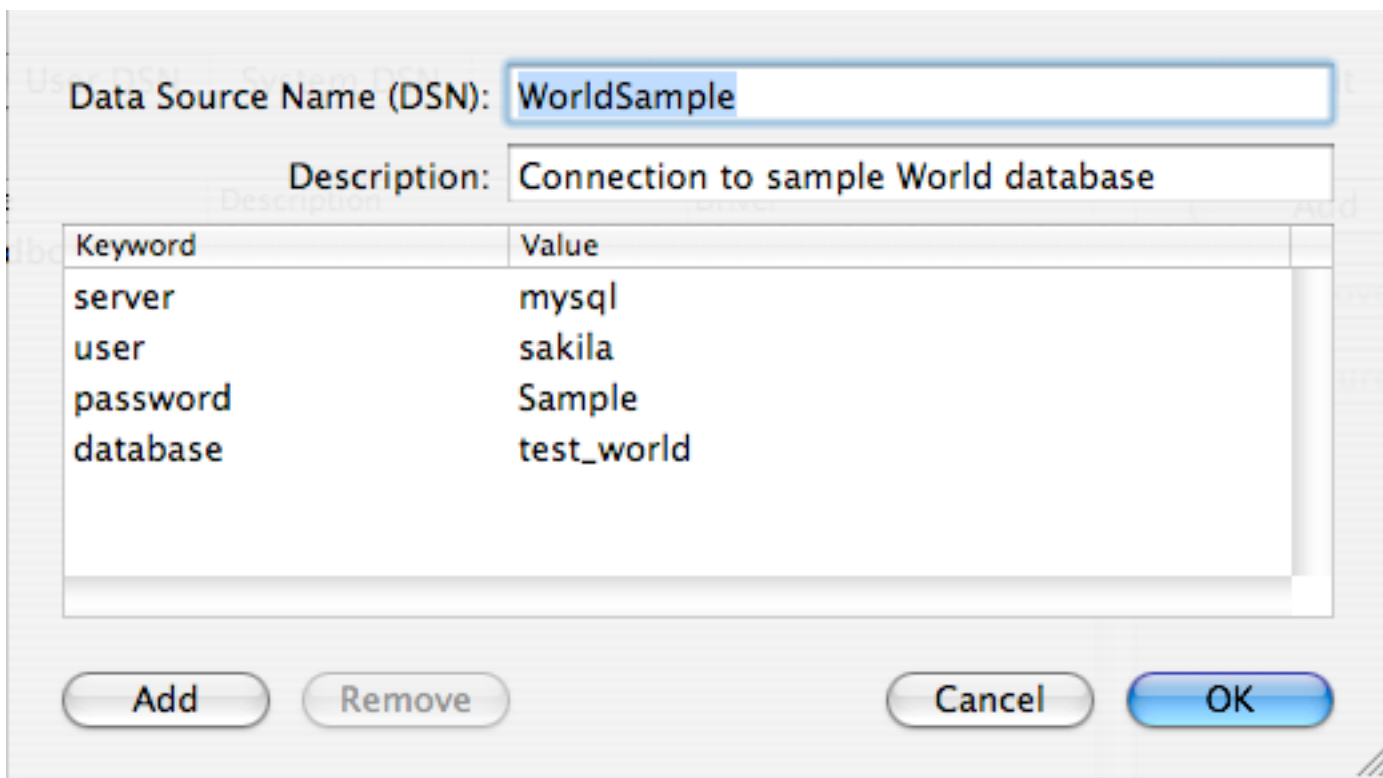

2. On the User DSN or System DSN panel, click **Add**.
3. Select the Connector/ODBC driver and click **OK**.
4. You will be presented with the **Data Source Name** dialog. Enter the **Data Source Name** and an optional **Description** for the DSN.

5. Click **Add** to add a new keyword/value pair to the panel. Configure at least four pairs to specify the [server](#), [username](#), [password](#) and [database](#) connection parameters. See [Section 22.1.4.2, "Connector/ODBC Connection Parameters"](#).
6. Click **OK** to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:

You can configure other ODBC options in your DSN by adding further keyword/value pairs and setting the corresponding values. See [Section 22.1.4.2, “Connector/ODBC Connection Parameters”](#).

22.1.4.5. Configuring a Connector/ODBC DSN on Unix

On [Unix](#), you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc3` as the DSN name for Connector/ODBC 3.51:

```

;
; odbc.ini configuration for Connector/ODBC and Connector/ODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc3      = MyODBC 3.51 Driver DSN

[myodbc3]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION      = 3
SOCKET      =

[Default]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test

```

```
OPTION      = 3
SOCKET      =
```

Refer to the [Section 22.1.4.2, “Connector/ODBC Connection Parameters”](#), for the list of connection parameters that can be supplied.

Note

If you are using `unixODBC`, you can use the following tools to set up the DSN:

- `ODBCConfig` GUI tool ([HOWTO: ODBCConfig](#))
- `odbcinst`

In some cases when using `unixODBC`, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

22.1.4.6. Connecting Without a Predefined DSN

You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for Connector/ODBC using DSN-Less connections:

For Connector/ODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
"SERVER=localhost;"
"DATABASE=test;"
"USER=venu;"
"PASSWORD=venu;"
"OPTION=3;"
```

Note. On Mac OS X, you might need to specify the full path to the Connector/ODBC driver library.

Refer to [Section 22.1.4.2, “Connector/ODBC Connection Parameters”](#) for the list of connection parameters that can be supplied.

22.1.4.7. ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling

connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

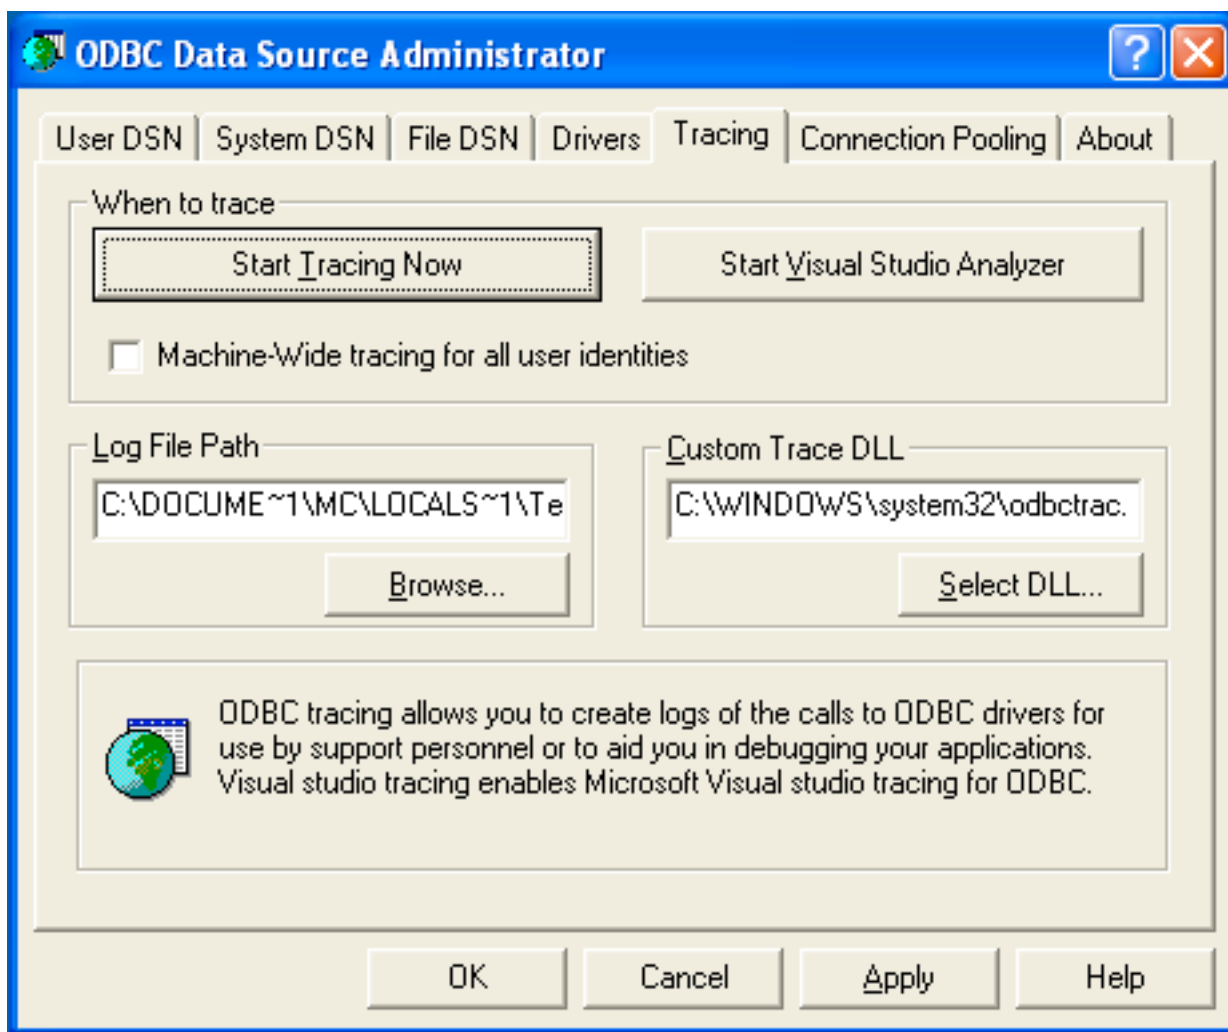

22.1.4.8. Getting an ODBC Trace File

If you encounter difficulties or problems with Connector/ODBC, start by making a log file from the [ODBC Manager](#) and Connector/ODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

22.1.4.8.1. Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The [Tracing](#) tab of the ODBC Data Source Administrator dialog box lets you configure the way ODBC function calls are traced.

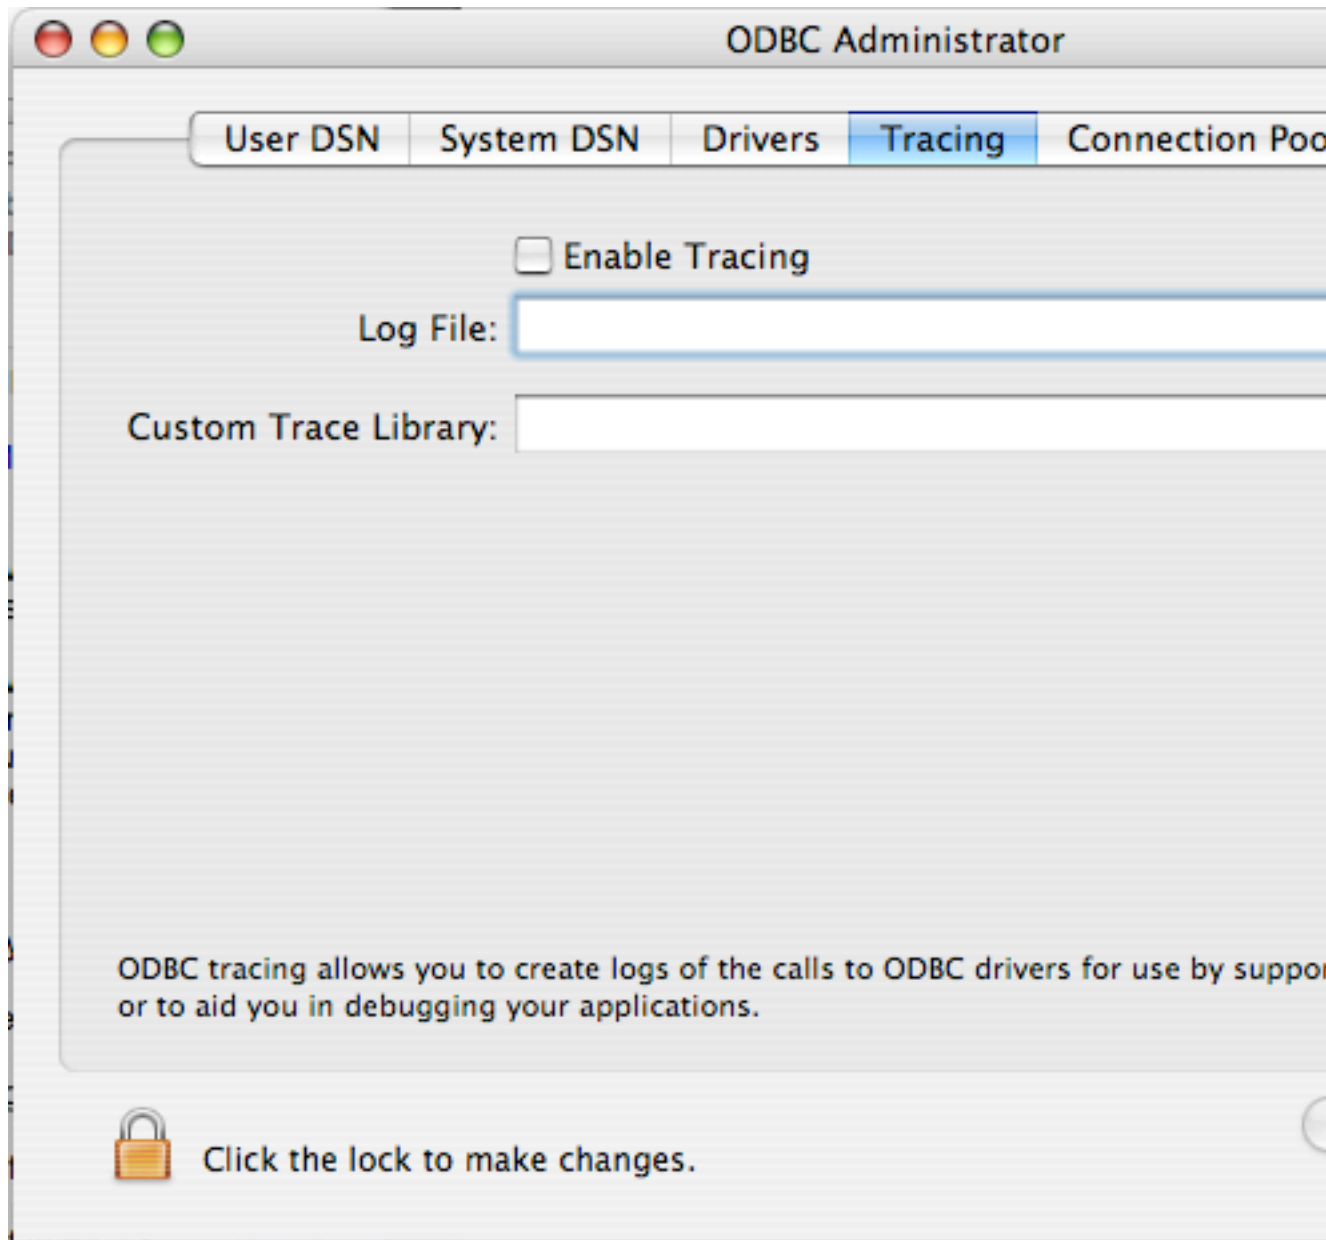

2. When you activate tracing from the [Tracing](#) tab, the [Driver Manager](#) logs all ODBC function calls for all subsequently run applications.

3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
4. Tracing ceases only after you click [Stop Tracing Now](#). Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

22.1.4.8.2. Enabling ODBC Tracing on Mac OS X

To enable the trace option on Mac OS X 10.3 or later, use the [Tracing](#) tab within ODBC Administrator .

1. Open the ODBC Administrator.
2. Select the [Tracing](#) tab.

3. Select the [Enable Tracing](#) check box.

4. Enter the location to save the Tracing log. To append information to an existing log file, click the **Choose...** button.

22.1.4.8.3. Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix, add the `trace` option to the ODBC configuration:

1. On Unix, explicitly set the `Trace` option in the `ODBC.INI` file.

Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

```
TraceFile = /tmp/odbc.trace
Trace     = 1
```

`TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at [HOWTO-ODBCConfig](#).

22.1.4.8.4. Enabling a Connector/ODBC Log

To generate a Connector/ODBC log, do the following:

1. Within Windows, enable the `Trace Connector/ODBC` option flag in the Connector/ODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the `myodbc.dll` driver, see [Section 22.1.4.3.3, "Troubleshooting ODBC Connection Problems"](#).

On Mac OS X, Unix, or if you are using a DSN-less connection, either supply `OPTION=4` in the connection string, or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the Connector/ODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see [Section 22.1.8.1, "Connector/ODBC Community Support"](#).

22.1.5. Connector/ODBC Examples

Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

22.1.5.1. Basic Connector/ODBC Application Steps

Interacting with a MySQL server from an applications using the Connector/ODBC typically involves the following operations:

- Configure the Connector/ODBC DSN.
- Connect to MySQL server.
- Initialization operations.
- Execute SQL statements.
- Retrieve results.

- Perform [transactions](#).
- Disconnect from the server.

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

22.1.5.2. Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC

A typical situation where you would install Connector/ODBC is to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you connect to system ALPHA from system BETA with a user name and password of `myuser` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a user name of `myuser` that can connect from system BETA using a password of `myuser` to the database `test`:

```
GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
```

For more information about MySQL privileges, refer to [Section 6.3, "MySQL User Account Management"](#).

On system BETA (the Connector/ODBC client), follow these steps:

1. Configure a Connector/ODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

| Parameter | Value | Comment |
|-----------|-------------|---|
| DSN | remote_test | A name to identify the connection. |
| SERVER | ALPHA | The address of the remote server. |
| DATABASE | test | The name of the default database. |
| USER | myuser | The user name configured for access to this database. |
| PASSWORD | mypassword | The password for <code>myuser</code> . |

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See [Section 22.1.4.8, "Getting an ODBC Trace File"](#), for more information.

22.1.5.3. Connector/ODBC and Third-Party ODBC Tools

Once you have configured your Connector/ODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using Connector/ODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

Connector/ODBC has been tested with the following applications:

| Publisher | Application | Notes |
|------------------|-----------------|--------------------------------|
| Adobe | ColdFusion | Formerly Macromedia ColdFusion |
| Borland | C++ Builder | |
| | Builder 4 | |
| | Delphi | |
| Business Objects | Crystal Reports | |

| Publisher | Application | Notes |
|---------------------|------------------------------|---|
| Claris | Filemaker Pro | |
| Corel | Paradox | |
| Computer Associates | Visual Objects | Also known as CAVO |
| | AllFusion ERwin Data Modeler | |
| Gupta | Team Developer | Previously known as Centura Team Developer; Gupta SQL/Windows |
| Gensym | G2-ODBC Bridge | |
| Inline | iHTML | |
| Lotus | Notes | Versions 4.5 and 4.6 |
| Microsoft | Access | |
| | Excel | |
| | Visio Enterprise | |
| | Visual C++ | |
| | Visual Basic | |
| | ODBC.NET | Using C#, Visual Basic, C++ |
| | FoxPro | |
| Visual Interdev | | |
| OpenOffice.org | OpenOffice.org | |
| Perl | DBD::ODBC | |
| Pervasive Software | DataJunction | |
| Sambar Technologies | Sambar Server | |
| SPSS | SPSS | |
| SoftVelocity | Clarion | |
| SQLExpress | SQLExpress for Xbase++ | |
| Sun | StarOffice | |
| SunSystems | Vision | |
| Sybase | PowerBuilder | |
| | PowerDesigner | |
| theKompany.com | Data Architect | |

If you know of any other applications that work with Connector/ODBC, please send mail to myodbc@lists.mysql.com about them.

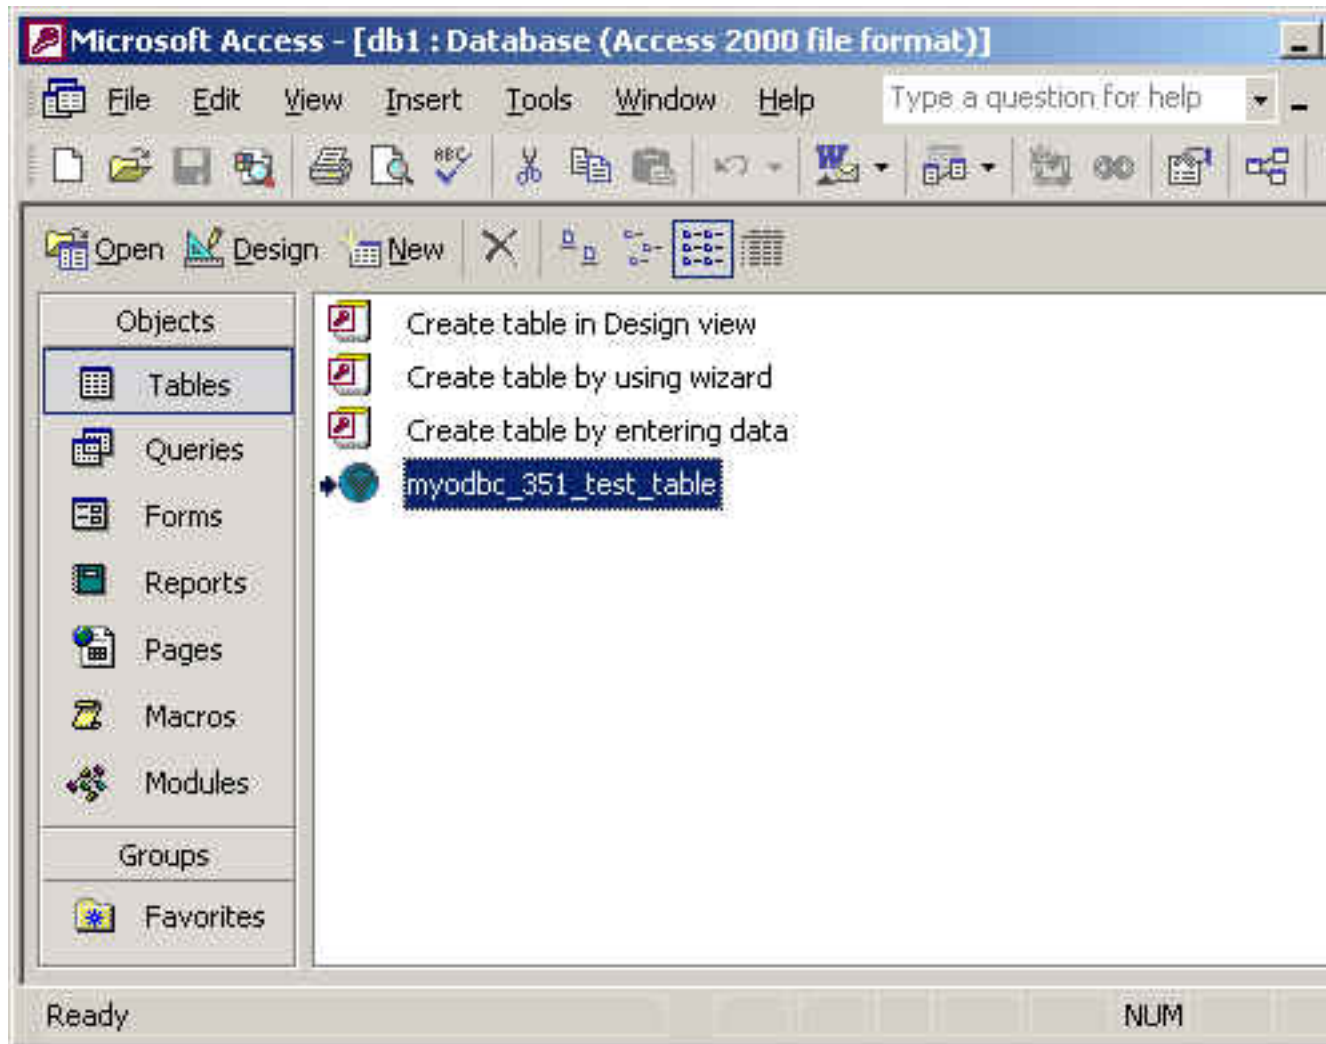

22.1.5.4. Using Connector/ODBC with Microsoft Access

You can use MySQL database with Microsoft Access using Connector/ODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

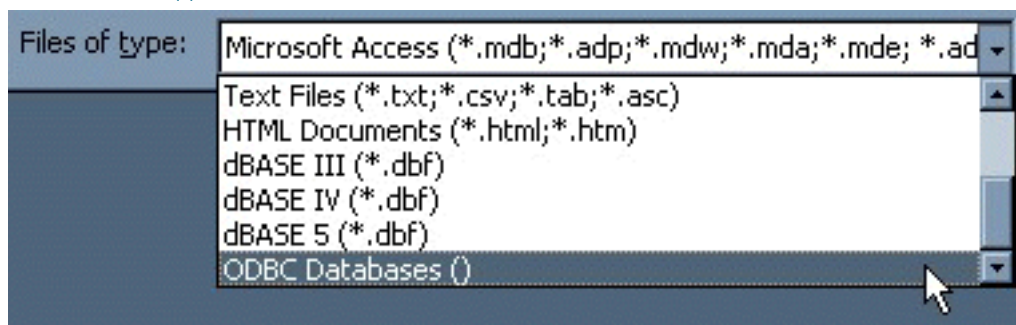

22.1.5.4.1. Exporting Access Data to MySQL

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the [table](#) or [query](#) to export, and then in the [File](#) menu, select [Export](#).
3. In the [Export Object Type Object name To](#) dialog box, in the [Save As Type](#) box, select [ODBC Databases \(\)](#) as shown here:

4. In the [Export](#) dialog box, enter a name for the file (or use the suggested name), and then select [OK](#).

5. The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the Connector/ODBC or Connector/ODBC 3.51 data source to export to. To define a new data source for Connector/ODBC, please [Section 22.1.4.3, “Configuring a Connector/ODBC DSN on Windows”](#).

**Note**

Ensure that the information that you are exporting to the MySQL table is valid for the corresponding MySQL data types. Values that are outside of the supported range of the MySQL data type but valid within Access may trigger an “overflow” error during the export.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

22.1.5.4.2. Importing MySQL Data to Access

To import a table or tables from MySQL to Access, follow these instructions:

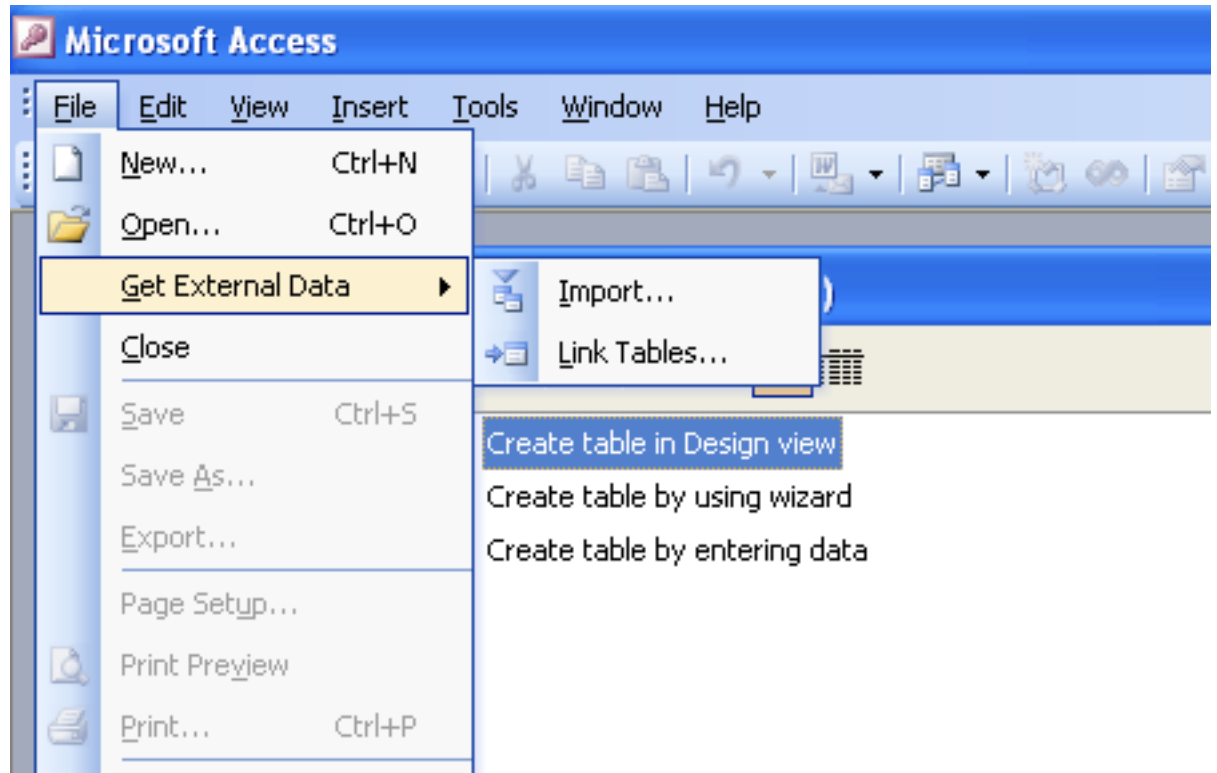

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the **File** menu, point to **Get External Data**, and then click **Import**.
3. In the **Import** dialog box, in the Files Of Type box, select **ODBC Databases ()**. The Select Data Source dialog box lists the defined data sources **The Select Data Source** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click **OK**.
5. Microsoft Access connects to the MySQL server through **ODBC data source** and displays the list of tables that you can **import**.
6. Click each table to **import**, and then click **OK**.

22.1.5.4.3. Using Microsoft Access as a Front-end to MySQL

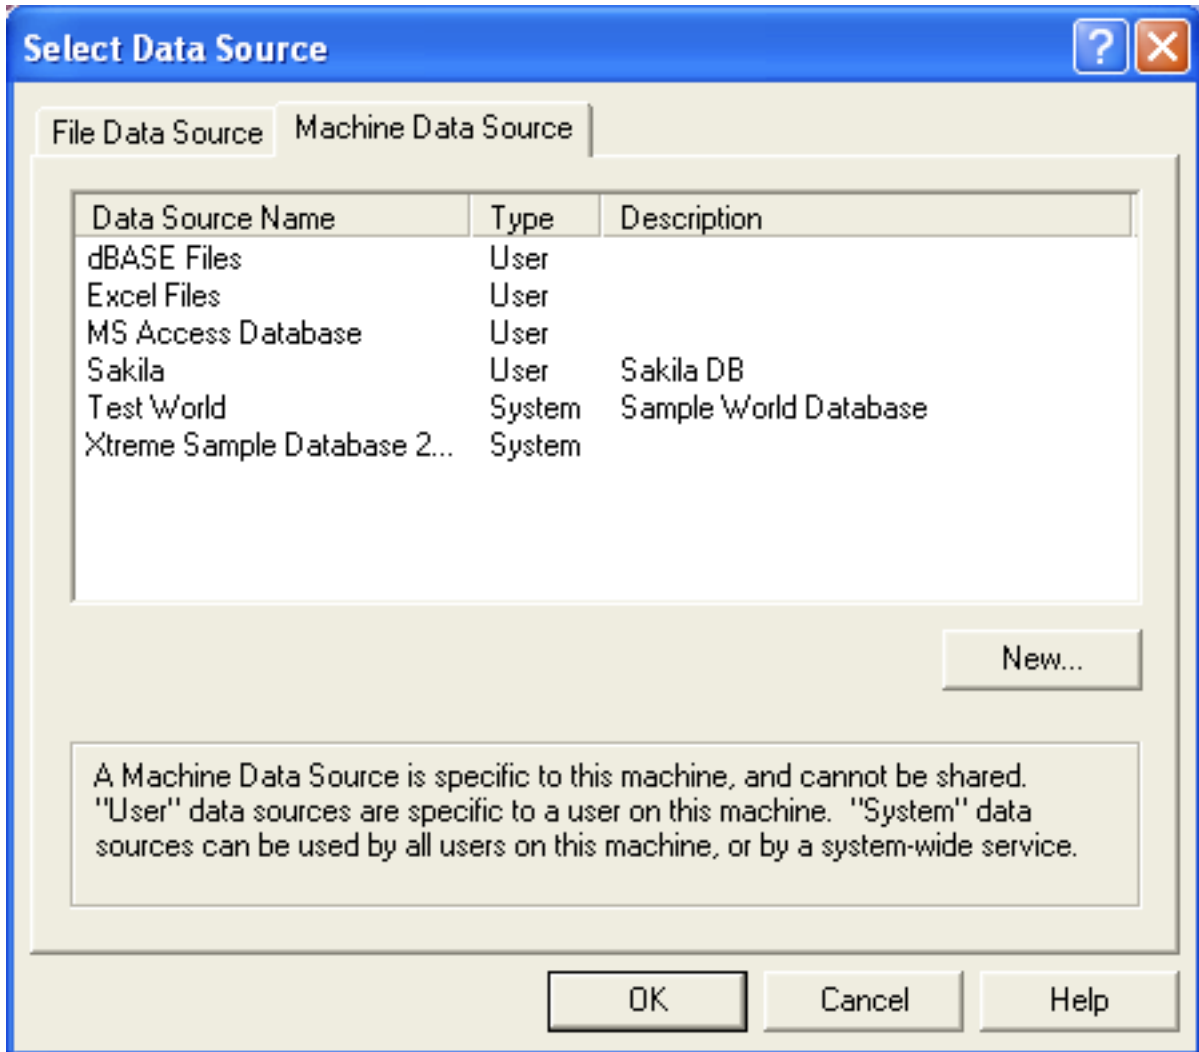

You can use Microsoft Access as a front end to a MySQL database by linking tables within your Microsoft Access database to tables that exist within your MySQL database. When a query is requested on a table within Access, ODBC is used to execute the queries on the MySQL database instead.

To create a linked table:

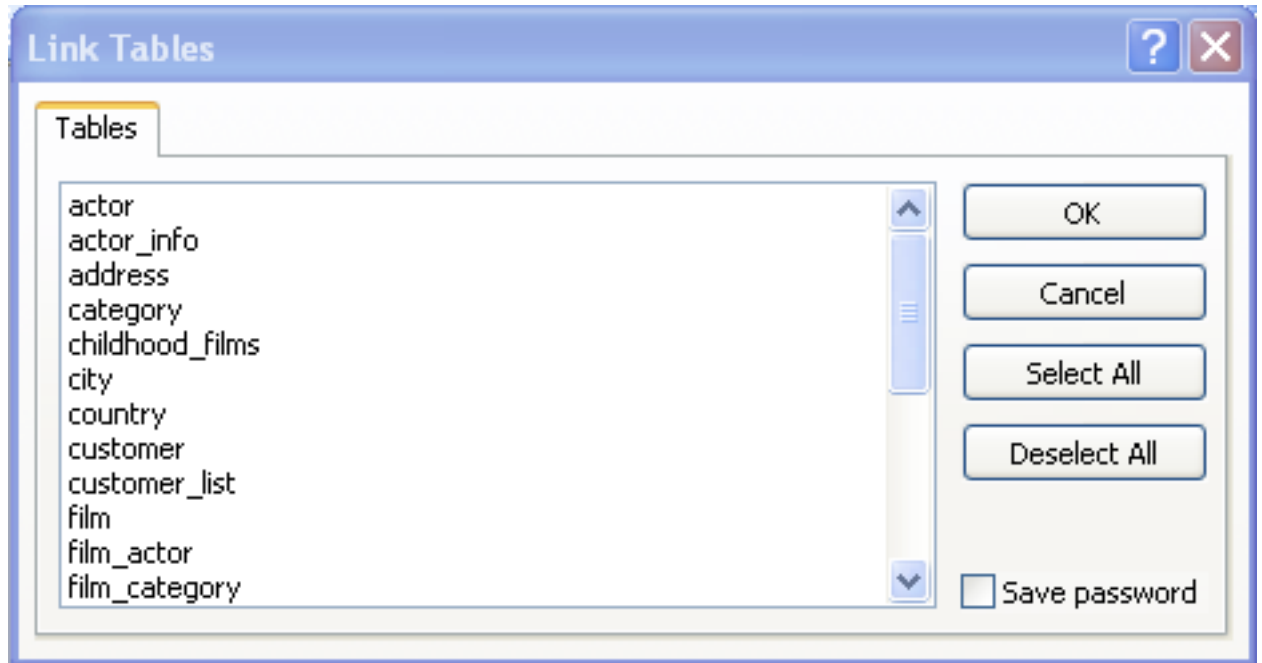

1. Open the Access database that you want to link to MySQL.
2. From the **File**, choose **Get External Data->Link Tables**.

3. From the browser, choose **ODBC Databases ()** from the **Files of type** pop-up.
4. In the **Select Data Source** window, choose an existing DSN, either from a **File Data Source** or **Machine Data Source**. You can also create a new DSN using the **New...** button. For more information on creating a DSN see [Section 22.1.4.3, "Configuring a Connector/ODBC DSN on Windows"](#).

5. In the **Link Tables** dialog, select one or more tables from the MySQL database. A link will be created to each table that you select from this list.

6. If Microsoft Access is unable to determine the unique record identifier for a table automatically then it may ask you to confirm the column, or combination of columns, to be used to uniquely identify each row from the source table. Select the columns to use and click **OK**.

Once the process has been completed, you can now build interfaces and queries to the linked tables just as you would for any Access database.

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

To view or refresh links:

1. Open the database that contains links to MySQL tables.
2. On the **Tools** menu, point to **Add-ins** (**Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the check box for the tables whose links you want to refresh.
4. Click **OK** to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the **Select New Location of <table name>** dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

To change the path for a set of linked tables:

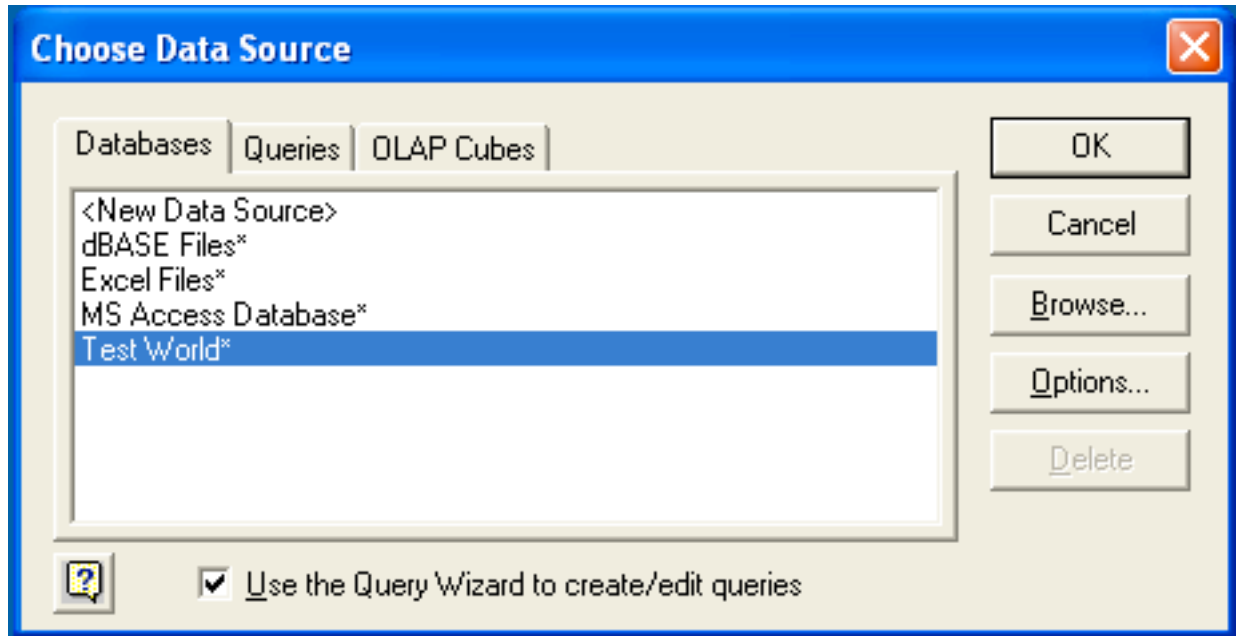

1. Open the database that contains links to tables.
2. On the **Tools** menu, point to **Add-ins** (**Database Utilities** in Access 2000 or newer), and then click **Linked Table Manager**.
3. Select the **Always Prompt For A New Location** check box.
4. Select the check box for the tables whose links you want to change, and then click **OK**.
5. In the **Select New Location of <table name>** dialog box, specify the new location, click **Open**, and then click **OK**.

22.1.5.5. Using Connector/ODBC with Microsoft Word or Excel

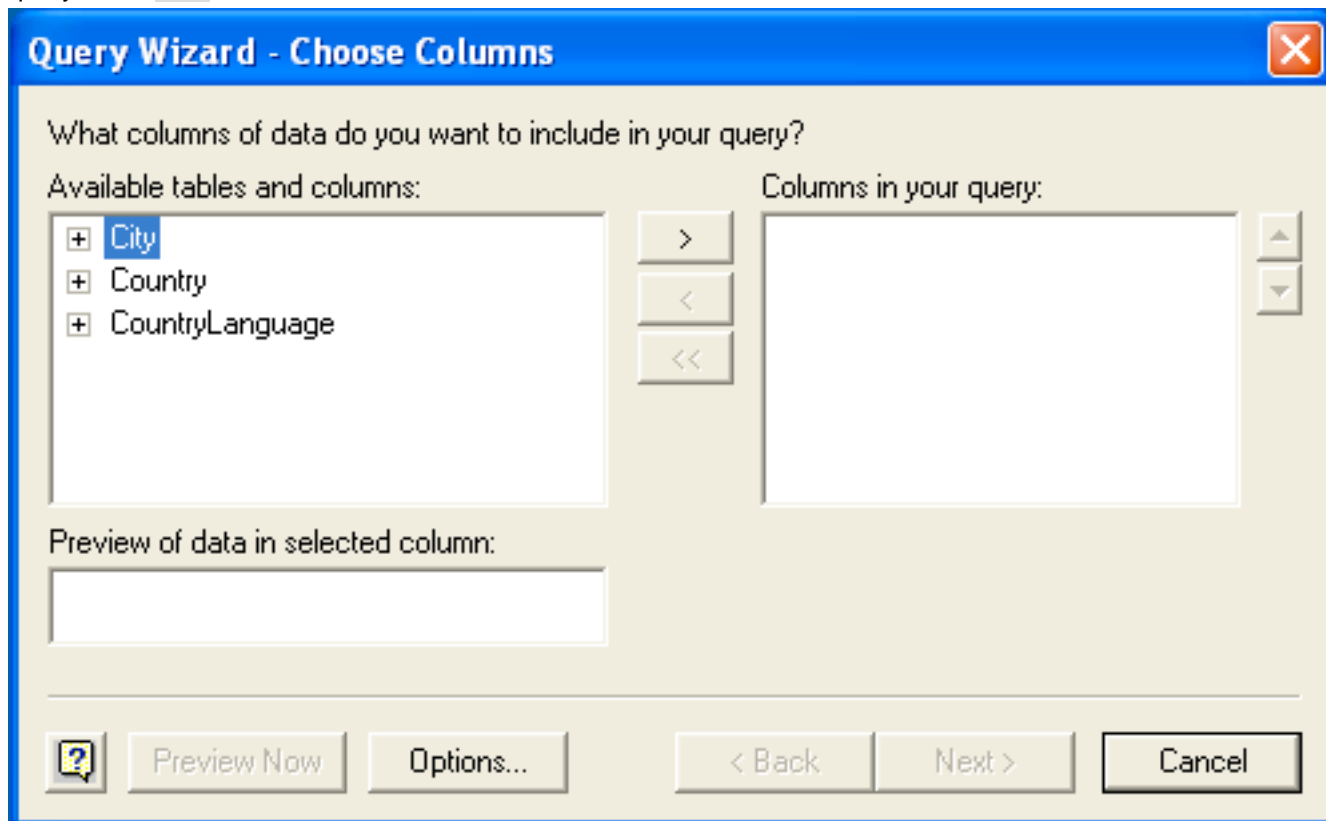

You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using Connector/ODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

With both applications, data is accessed and imported into the application using Microsoft Query, which lets you execute a query though an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in [Section 22.1.4, "Configuring Connector/ODBC"](#):

1. Create a new Worksheet.
2. From the **Data** menu, choose **Import External Data**, and then select **New Database Query**.
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.

4. Within the [Query Wizard](#), choose the columns to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a [SELECT](#) query. Click Next to continue.

5. You can filter rows from the query (the equivalent of a [WHERE](#) clause) using the [Filter Data](#) dialog. Click Next to continue.

Query Wizard - Filter Data

Filter the data to specify which rows to include in your query.
If you don't want to filter the data, click Next.

Column to filter:

- Name
- CountryCode
- District
- Population

Only include rows where:

Name

And Or

And Or

And Or

6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click Next to continue.

Query Wizard - Sort Order

Specify how you want your data sorted.
If you don't want to sort the data, click Next.

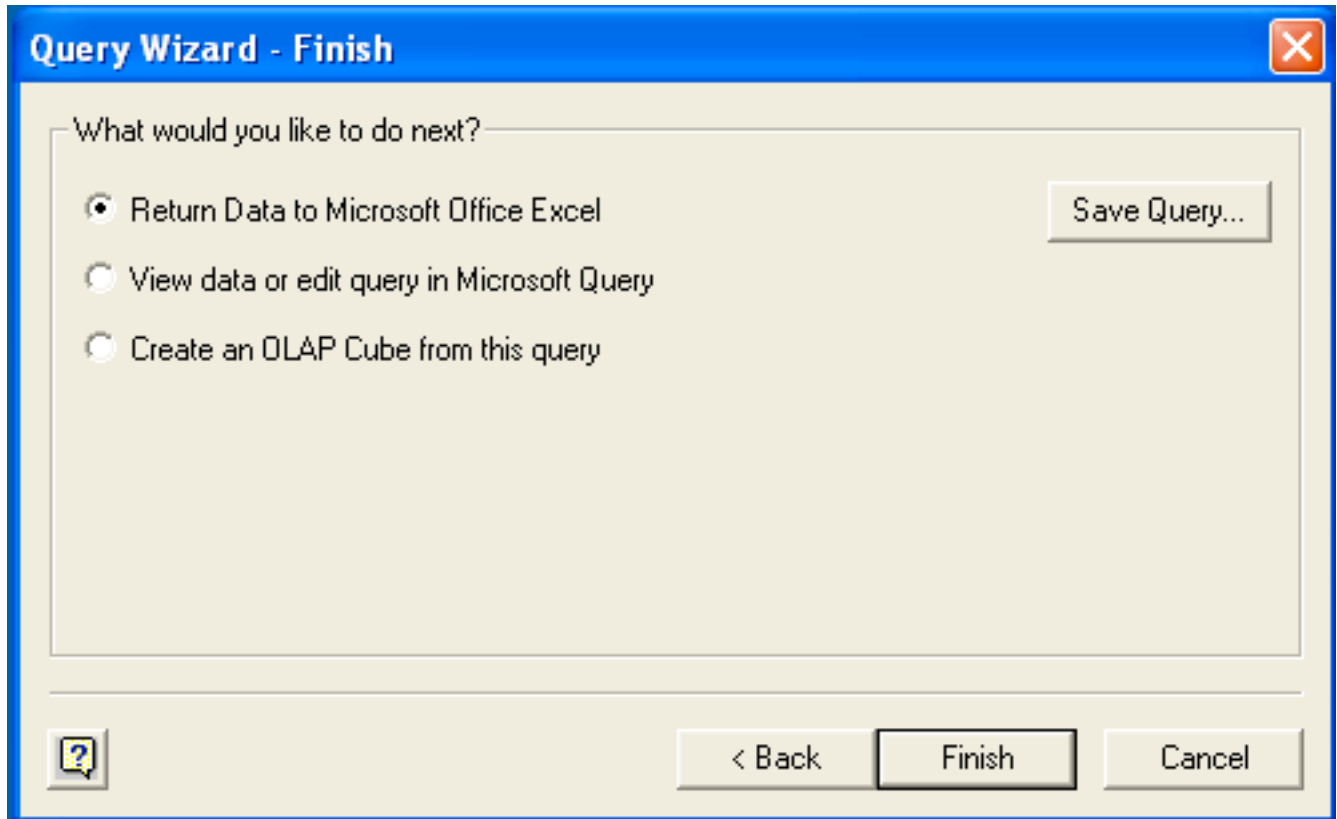

Sort by
Name Ascending Descending

Then by Ascending Descending

Then by Ascending Descending

< Back Next > Cancel

7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click **Finish**.

The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

22.1.5.6. Using Connector/ODBC with Crystal Reports

Crystal Reports can use an ODBC DSN to connect to a database from which you to extract data and information for reporting purposes.

Note

There is a known issue with certain versions of Crystal Reports where the application is unable to open and browse tables and fields through an ODBC connection. Before using Crystal Reports with MySQL, please ensure that you have update to the latest version, including any outstanding service packs and hotfixes. For more information on this issue, see the [Business\) Objects Knowledgebase](#) for more information.

For example, to create a simple crosstab report within Crystal Reports XI, follow these steps:

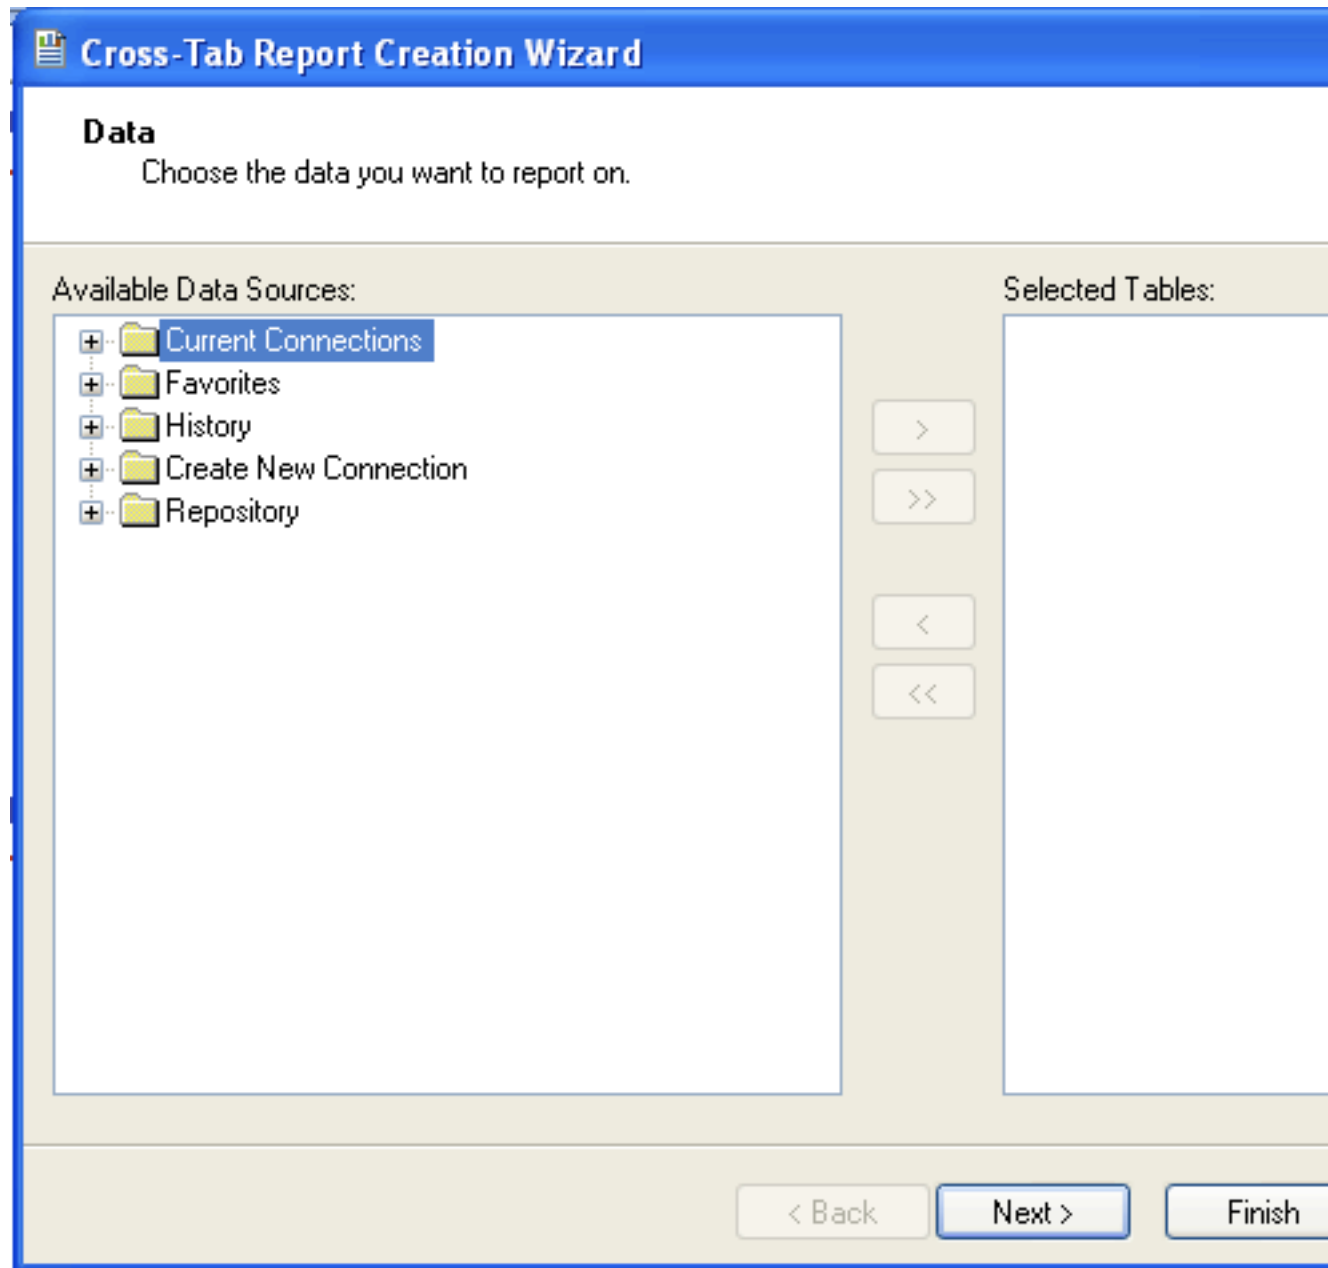

1. Create a DSN using the [Data Sources \(ODBC\)](#) tool. You can either specify a complete database, including user name and password, or you can build a basic DSN and use Crystal Reports to set the user name and password.

For the purposes of this example, a DSN that provides a connection to an instance of the MySQL Sakila sample database has been created.

2. Open Crystal Reports and create a new project, or an open an existing reporting project into which you want to insert data from your MySQL data source.

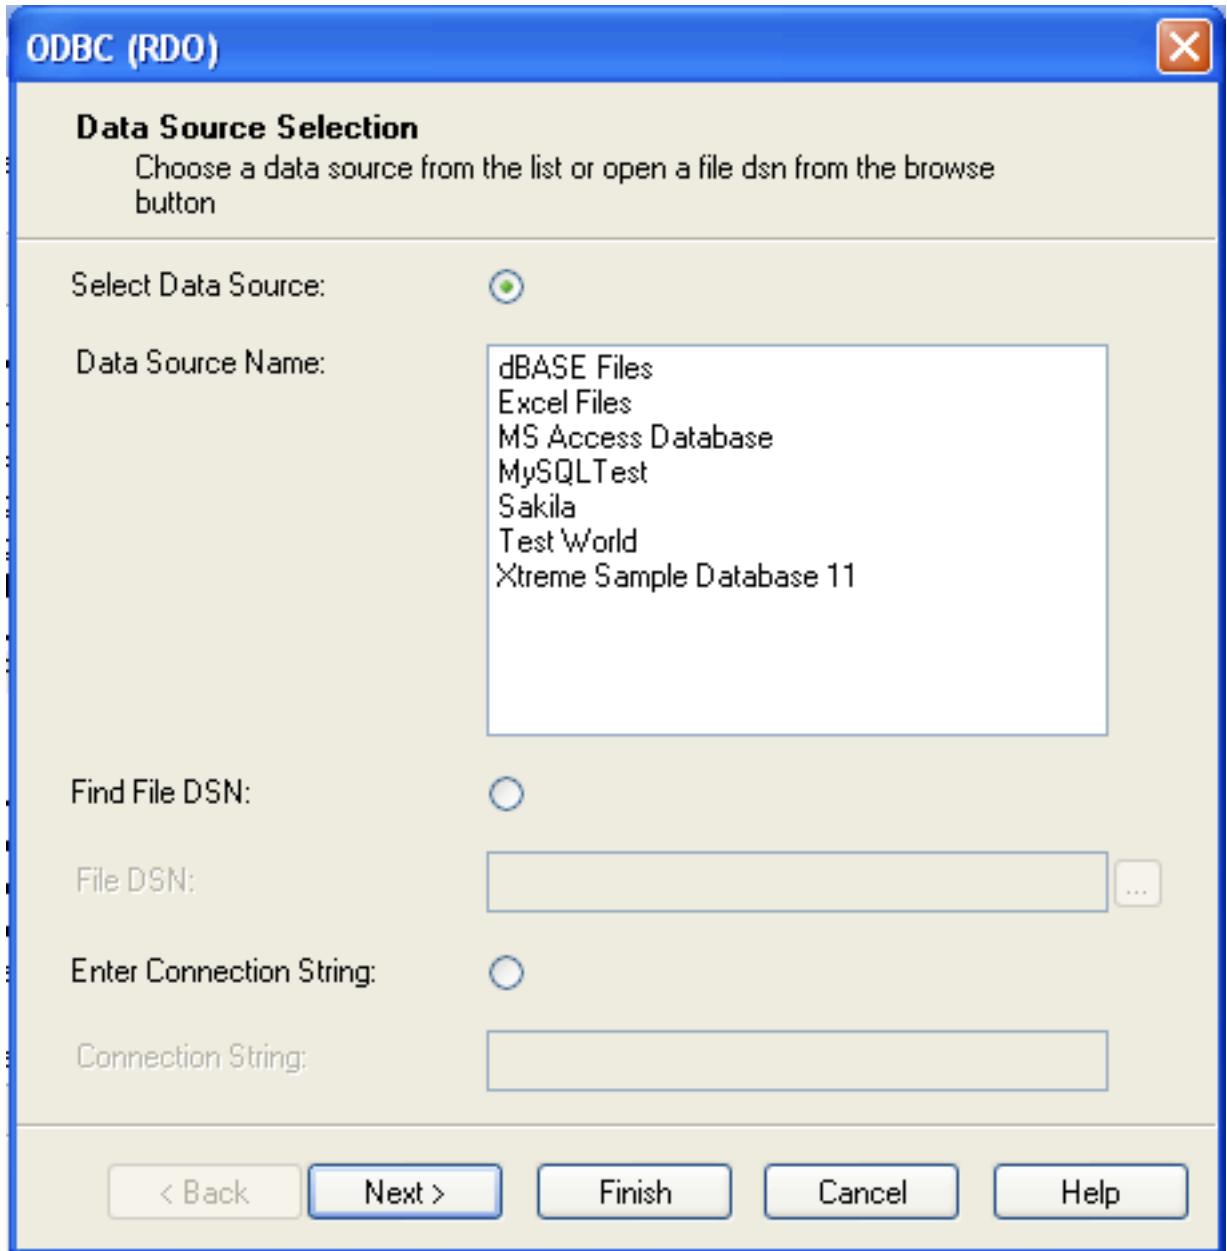

3. Start the Cross-Tab Report Wizard, either by clicking the option on the Start Page. Expand the **Create New Connection** folder, then expand the **ODBC (RDO)** folder to obtain a list of ODBC data sources.

You will be asked to select a data source.

4. When you first expand the **ODBC (RDO)** folder you will be presented the Data Source Selection screen. From here you can select either a pre-configured DSN, open a file-based DSN or enter and manual connection string. For this example, the **Sakila** DSN will be used.

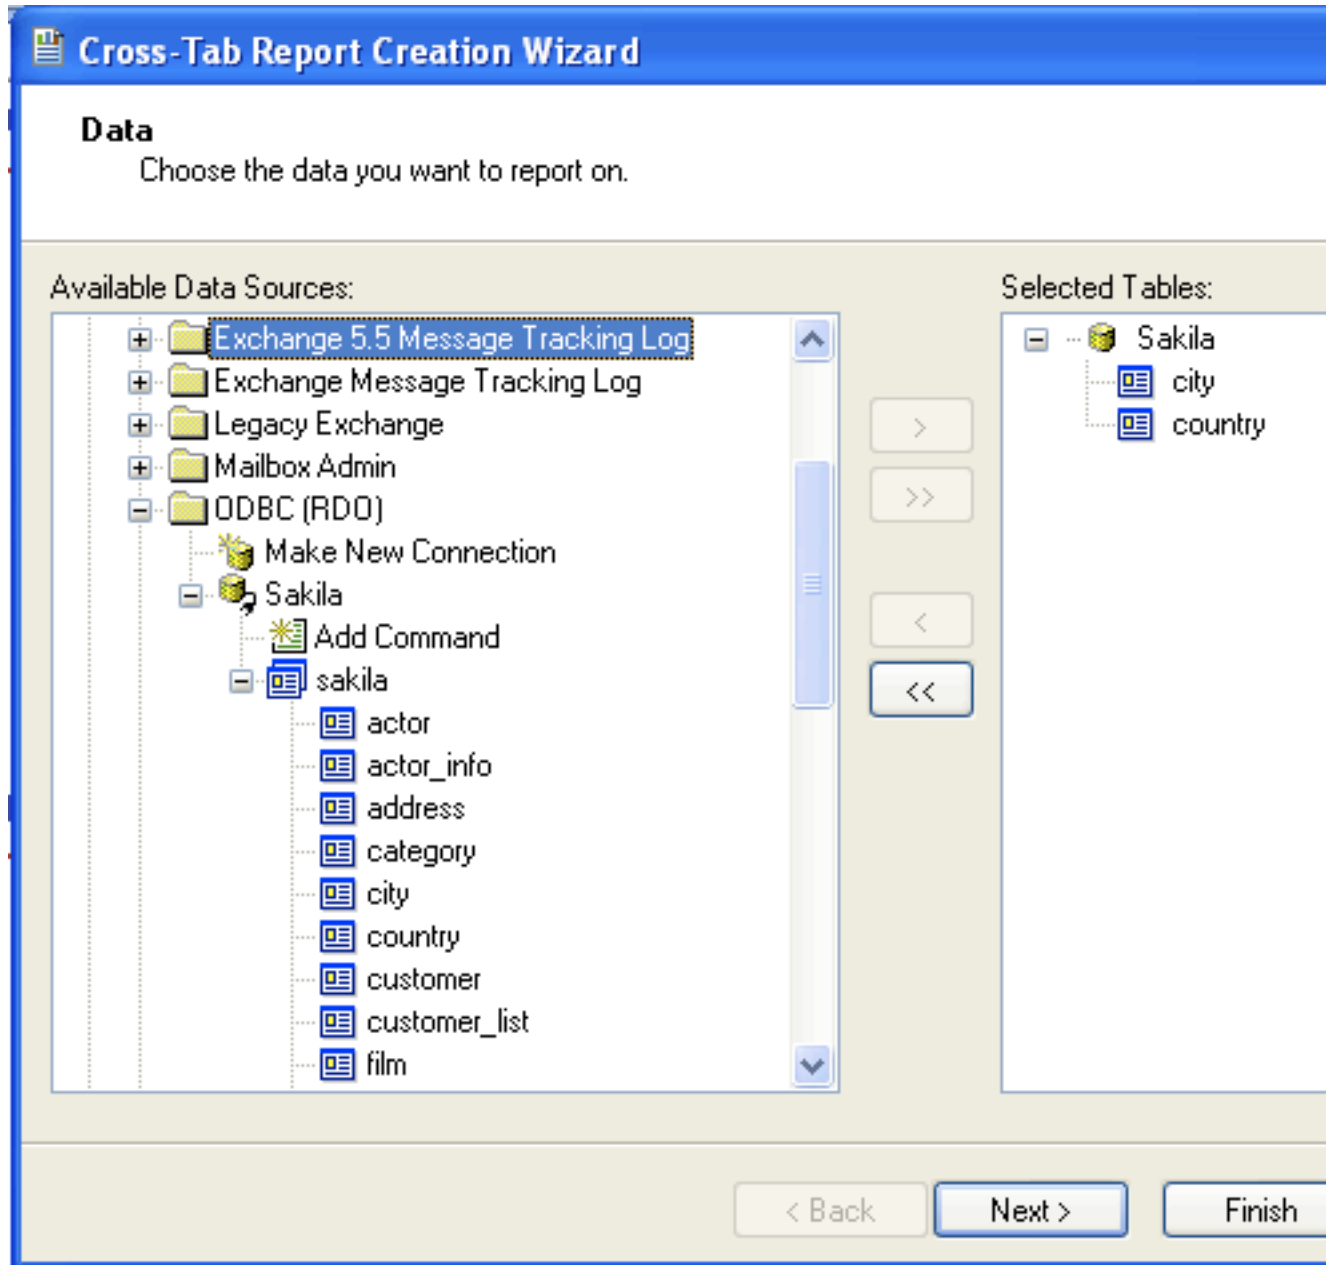

If the DSN contains a user name/password combination, or you want to use different authentication credentials, click **Next** to enter the user name and password that you want to use. Otherwise, click **Finish** to continue the data source selection wizard.

5. You will be returned the Cross-Tab Report Creation Wizard. You now need to select the database and tables that you want to include in your report. For our example, we will expand the selected Sakila database. Click the `city` table and use the `>` button to add the table to the report. Then repeat the action with the `country` table. Alternatively you can select multiple tables and add them to the report.

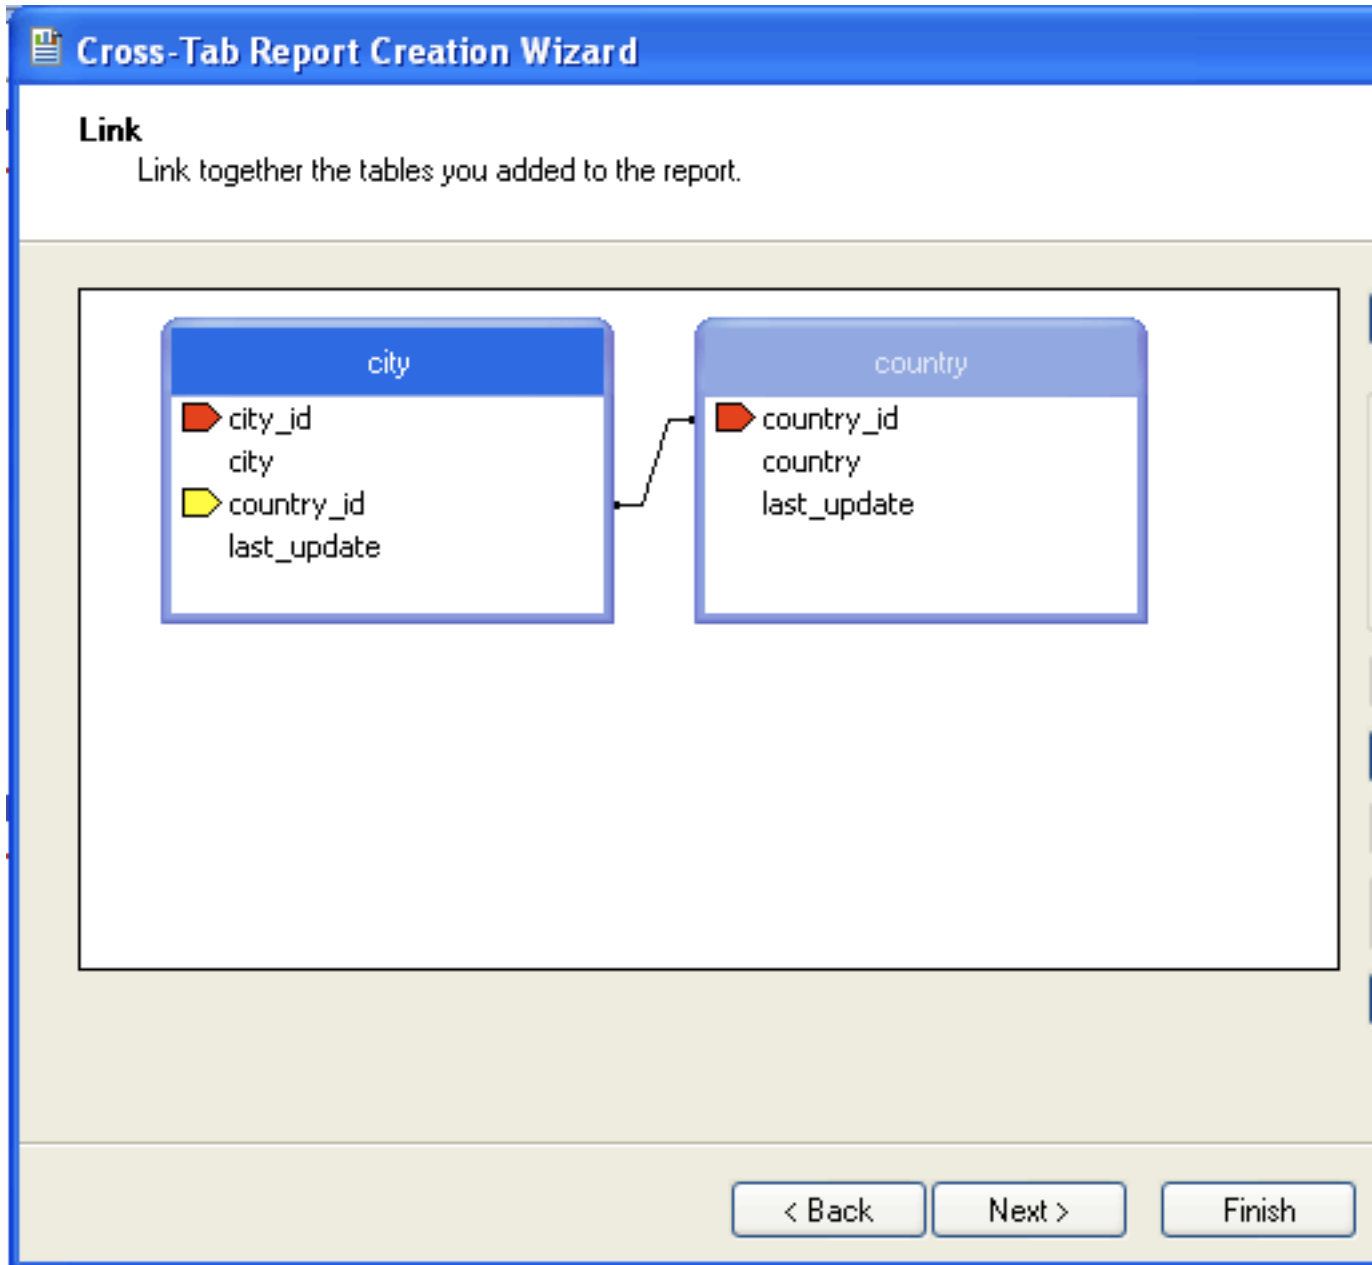

Finally, you can select the parent **Sakila** resource and add of the tables to the report.

Once you have selected the tables you want to include, click **Next** to continue.

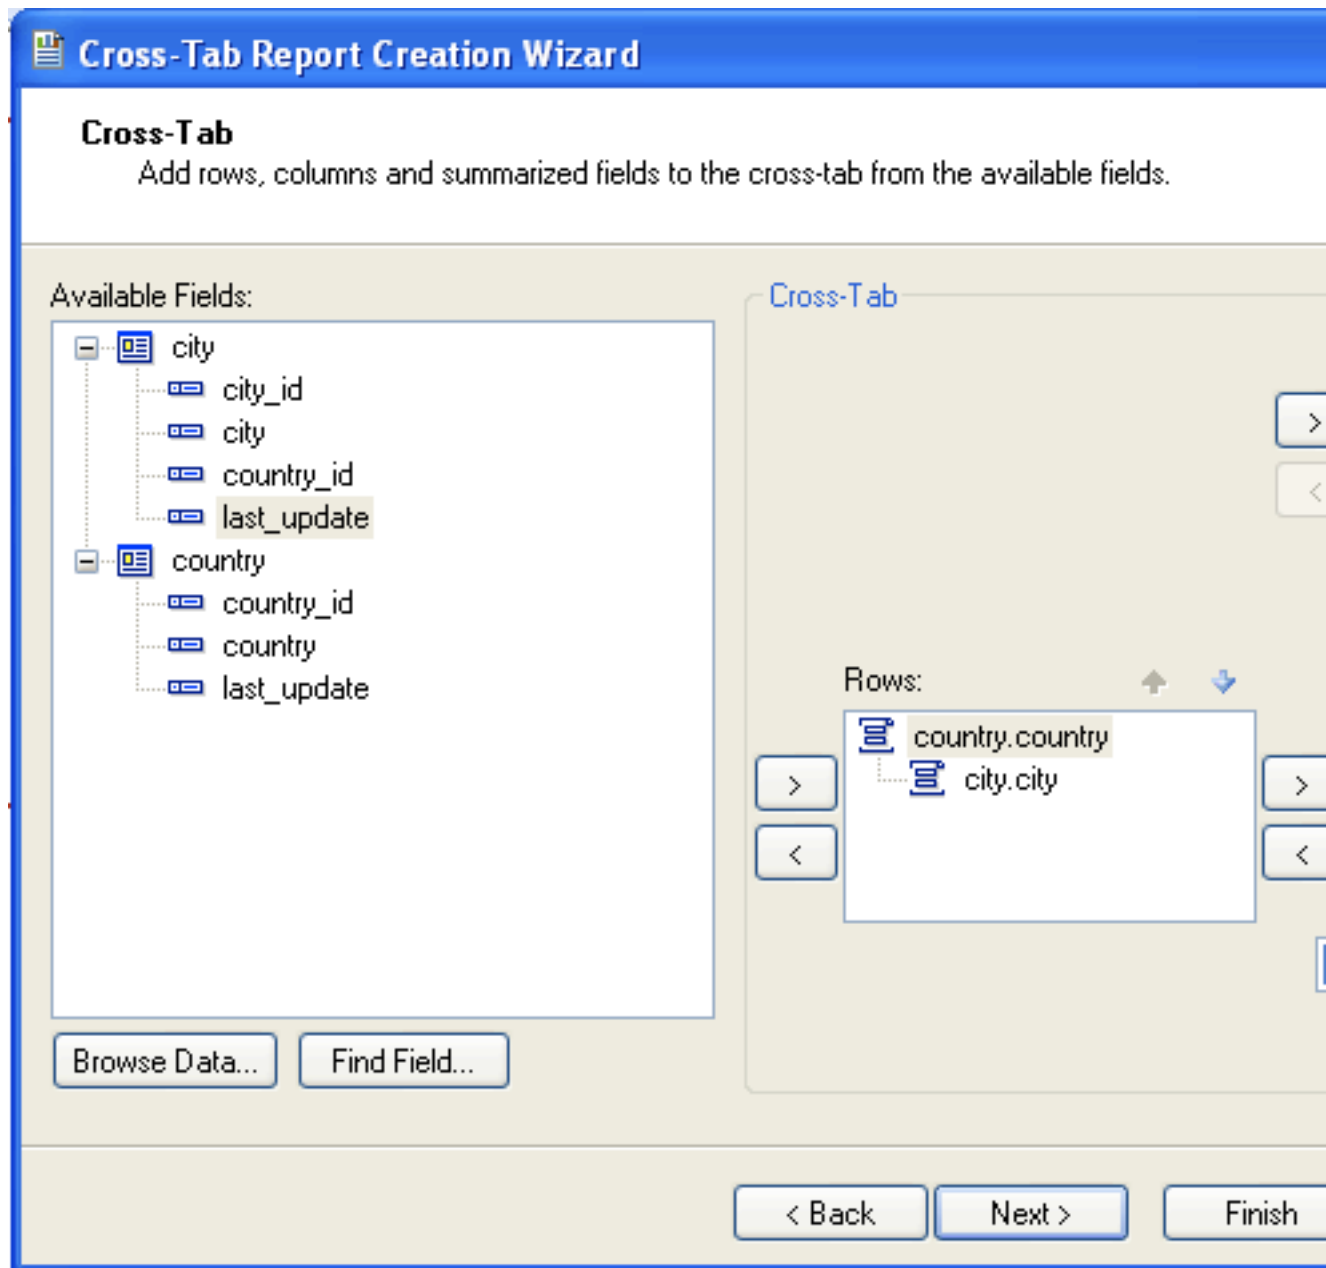

6. Crystal Reports will now read the table definitions and automatically identify the links between the tables. The identification of links between tables enables Crystal Reports to automatically lookup and summarize information based on all the tables in the database according to your query. If Crystal Reports is unable to perform the linking itself, you can manually create the links between fields in the tables you have selected.

Click **Next** to continue the process.

7. You can now select the columns and rows that to include within the Cross-Tab report. Drag and drop or use the **>** buttons to add fields to each area of the report. In the example shown, we will report on cities, organized by country, incorporating a count of the number of cities within each country. If you want to browse the data, select a field and click the **Browse Data...** button.

Click **Next** to create a graph of the results. Since we are not creating a graph from this data, click **Finish** to generate the report.

8. The finished report will be shown, a sample of the output from the Sakila sample database is shown below.

| | | Total |
|-----------------------|-----------------------|-------|
| Total | | 600 |
| Afghanistan | Total | 1 |
| | Kabul | 1 |
| Algeria | Total | 3 |
| | Batna | 1 |
| | Bchar | 1 |
| | Skikda | 1 |
| American Samoa | Total | 1 |
| | Tafuna | 1 |
| Angola | Total | 2 |
| | Benguela | 1 |
| | Namibe | 1 |
| Anguilla | Total | 1 |
| | South Hill | 1 |
| Argentina | Total | 13 |
| | Almirante Brow | 1 |

Once the ODBC connection has been opened within Crystal Reports, you can browse and add any fields within the available tables into your reports.

22.1.5.7. Connector/ODBC Programming

With a suitable ODBC Manager and the Connector/ODBC driver installed, any programming language or environment that can support ODBC can connect to a MySQL database through Connector/ODBC.

This includes, but is not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

22.1.5.7.1. Using Connector/ODBC with Visual Basic Using ADO, DAO and RDO

This section contains simple examples of the use of Connector/ODBC with ADO, DAO and RDO.

22.1.5.7.1.1. ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using Connector/ODBC
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)," _
& "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
rs.Update
rs.Close

'rs update
```

```

rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub

```

22.1.5.7.1.2. DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```

Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};_"
& "SERVER=localhost;_"
& "DATABASE=test;_"
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")

```

```

queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

22.1.5.7.1.3. RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& "DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

```

```
cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub
```

22.1.5.7.2. Using Connector/ODBC with .NET

This section contains simple examples that demonstrate the use of Connector/ODBC drivers with ODBC.NET.

22.1.5.7.2.1. Using Connector/ODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```
/**
 * @sample      : mycon.cs
 * @purpose     : Demo sample for ODBC.NET using Connector/ODBC
 * @author      : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 */

/* build command
 *
 * csc /t:exe
 *      /out:mycon.exe mycon.cs
 *      /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
    class mycon
    {
        static void Main(string[] args)
        {
            try
            {
                //Connection string for Connector/ODBC 3.51
                string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
                    "SERVER=localhost;" +
                    "DATABASE=test;" +
                    "UID=venu;" +
                    "PASSWORD=venu;" +
                    "OPTION=3";

                //Connect to MySQL using Connector/ODBC
                OdbcConnection MyConnection = new OdbcConnection(MyConString);
                MyConnection.Open();

                Console.WriteLine("\n !!! success, connected successfully !!!\n");

                //Display connection information
                Console.WriteLine("Connection Information:");
                Console.WriteLine("\tConnection String:" +
                    MyConnection.ConnectionString);
                Console.WriteLine("\tConnection Timeout:" +
                    MyConnection.ConnectionTimeout);
                Console.WriteLine("\tDatabase:" +
                    MyConnection.Database);
                Console.WriteLine("\tDataSource:" +
                    MyConnection.DataSource);
                Console.WriteLine("\tDriver:" +
                    MyConnection.Driver);
                Console.WriteLine("\tServerVersion:" +
                    MyConnection.ServerVersion);

                //Create a sample table
                OdbcCommand MyCommand =
                    new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
                        MyConnection);
            }
            catch { }
        }
    }
}
```

Connector/ODBC Examples

```
MyCommand.ExecuteNonQuery();
MyCommand.CommandText =
    "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
MyCommand.ExecuteNonQuery();

//Insert
MyCommand.CommandText =
    "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
Console.WriteLine("INSERT, Total rows affected:" +
    MyCommand.ExecuteNonQuery());

//Insert
MyCommand.CommandText =
    "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
Console.WriteLine("INSERT, Total rows affected:" +
    MyCommand.ExecuteNonQuery());

//Insert
MyCommand.CommandText =
    "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
Console.WriteLine("INSERT, Total rows affected:" +
    MyCommand.ExecuteNonQuery());

//Update
MyCommand.CommandText =
    "UPDATE my_odbc_net SET id=999 WHERE id=20";
Console.WriteLine("Update, Total rows affected:" +
    MyCommand.ExecuteNonQuery());

//COUNT(*)
MyCommand.CommandText =
    "SELECT COUNT(*) as TRows FROM my_odbc_net";
Console.WriteLine("Total Rows:" +
    MyCommand.ExecuteScalar());

//Fetch
MyCommand.CommandText = "SELECT * FROM my_odbc_net";
OdbcDataReader MyDataReader;
MyDataReader = MyCommand.ExecuteReader();
while (MyDataReader.Read())
{
    if(string.Compare(MyConnection.Driver,"myodbc3.dll") == 0) {
        //Supported only by Connector/ODBC 3.51
        Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
            MyDataReader.GetString(1) + " " +
            MyDataReader.GetInt64(2));
    }
    else {
        //BIGINTs not supported by Connector/ODBC
        Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
            MyDataReader.GetString(1) + " " +
            MyDataReader.GetInt32(2));
    }
}

//Close all resources
MyDataReader.Close();
MyConnection.Close();
}
catch (OdbcException MyOdbcException) //Catch any ODBC exception ..
{
    for (int i=0; i < MyOdbcException.Errors.Count; i++)
    {
        Console.Write("ERROR #" + i + "\n" +
            "Message: " +
            MyOdbcException.Errors[i].Message + "\n" +
            "Native: " +
```

```
MyOdbcException.Errors[i].NativeError.ToString() + "\n" +  
"Source: " +  
MyOdbcException.Errors[i].Source + "\n" +  
"SQL: " +  
MyOdbcException.Errors[i].SQLState + "\n");  
    }  
    }  
}
```

22.1.5.7.2.2. Using Connector/ODBC with ODBC.NET and Visual Basic

The following sample creates a table `my_vb_net` and demonstrates the use in VB.

```

```

22.1.6. Connector/ODBC Reference

This section provides reference material for the Connector/ODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in Connector/ODBC, and the error codes returned by Connector/ODBC when a fault occurs.

22.1.6.1. Connector/ODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at <http://msdn.microsoft.com/en-us/library/ms714177.aspx>.

An application can call `SQLGetInfo` function to obtain conformance information about Connector/ODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

**Note**

For backward compatibility, the Connector/ODBC driver supports all deprecated functions.

The following tables list Connector/ODBC API calls grouped by task:

Table 22.6. ODBC API Calls for Connecting to a Data Source

| Function Name | Connector/ODBC Supports? | Standard | Purpose |
|-------------------------------|--------------------------|------------|---|
| <code>SQLAllocHandle</code> | Yes | ISO 92 | Obtains an environment, connection, statement, or descriptor handle. |
| <code>SQLConnect</code> | Yes | ISO 92 | Connects to a specific driver by data source name, user ID, and password. |
| <code>SQLDriverConnect</code> | Yes | ODBC | Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user. |
| <code>SQLAllocEnv</code> | Yes | Deprecated | Obtains an environment handle allocated from driver. |
| <code>SQLAllocConnect</code> | Yes | Deprecated | Obtains a connection handle |

Table 22.7. ODBC API Calls for Obtaining Information about a Driver and Data Source

| Function Name | Connector/ODBC Supports? | Standard | Purpose |
|------------------------------|--------------------------|----------|---|
| <code>SQLDataSources</code> | No | ISO 92 | Returns the list of available data sources, handled by the Driver Manager |
| <code>SQLDrivers</code> | No | ODBC | Returns the list of installed drivers and their attributes, handles by Driver Manager |
| <code>SQLGetInfo</code> | Yes | ISO 92 | Returns information about a specific driver and data source. |
| <code>SQLGetFunctions</code> | Yes | ISO 92 | Returns supported driver functions. |
| <code>SQLGetTypeInfo</code> | Yes | ISO 92 | Returns information about supported data types. |

Table 22.8. ODBC API Calls for Setting and Retrieving Driver Attributes

| Function Name | Connector/ODBC Supports? | Standard | Purpose |
|--------------------------------|--------------------------|----------|--|
| <code>SQLSetConnectAttr</code> | Yes | ISO 92 | Sets a connection attribute. |
| <code>SQLGetConnectAttr</code> | Yes | ISO 92 | Returns the value of a connection attribute. |

| Function Name | Connector/ ODBC Supports? | Standard | Purpose |
|-------------------------------------|---------------------------------|------------|--|
| SQLSetConnectOption | Yes | Deprecated | Sets a connection option |
| SQLGetConnectOption | Yes | Deprecated | Returns the value of a connection option |
| SQLSetEnvAttr | Yes | ISO 92 | Sets an environment attribute. |
| SQLGetEnvAttr | Yes | ISO 92 | Returns the value of an environment attribute. |
| SQLSetStmtAttr | Yes | ISO 92 | Sets a statement attribute. |
| SQLGetStmtAttr | Yes | ISO 92 | Returns the value of a statement attribute. |
| SQLSetStmtOption | Yes | Deprecated | Sets a statement option |
| SQLGetStmtOption | Yes | Deprecated | Returns the value of a statement option |

Table 22.9. ODBC API Calls for Preparing SQL Requests

| Function Name | Connector/ ODBC Supports? | Standard | Purpose |
|-------------------------------------|---------------------------------|------------|--|
| SQLAllocStmt | Yes | Deprecated | Allocates a statement handle |
| SQLPrepare | Yes | ISO 92 | Prepares an SQL statement for later execution. |
| SQLBindParameter | Yes | ODBC | Assigns storage for a parameter in an SQL statement. Connector/ODBC 5.2 adds support for “out” and “inout” parameters, through the SQL_PARAM_OUTPUT or SQL_PARAM_INPUT_OUTPUT type specifiers. (“Out” and “inout” parameters are not supported for LONGTEXT and LONGBLOB columns.) |
| SQLGetCursorName | Yes | ISO 92 | Returns the cursor name associated with a statement handle. |
| SQLSetCursorName | Yes | ISO 92 | Specifies a cursor name. |
| SQLSetScrollOptions | Yes | ODBC | Sets options that control cursor behavior. |

Table 22.10. ODBC API Calls for Submitting Requests

| Function Name | Connector/ ODBC Supports? | Standard | Purpose |
|----------------------------------|---------------------------------|----------|--|
| SQLExecute | Yes | ISO 92 | Executes a prepared statement. |
| SQLExecDirect | Yes | ISO 92 | Executes a statement |
| SQLNativeSql | Yes | ODBC | Returns the text of an SQL statement as translated by the driver. |
| SQLDescribeParam | Yes | ODBC | Returns the description for a specific parameter in a statement. |
| SQLNumParams | Yes | ISO 92 | Returns the number of parameters in a statement. |
| SQLParamData | Yes | ISO 92 | Used in conjunction with SQLPutData to supply parameter data at execution time. (Useful for long data values.) |

| Function Name | Connector/ODBC Supports? | Standard | Purpose |
|-------------------------|--------------------------|----------|---|
| <code>SQLPutData</code> | Yes | ISO 92 | Sends part or all of a data value for a parameter. (Useful for long data values.) |

Table 22.11. ODBC API Calls for Retrieving Results and Information about Results

| Function Name | Connector/ODBC Supports? | Standard | Purpose |
|--------------------------------|--------------------------|------------|---|
| <code>SQLRowCount</code> | Yes | ISO 92 | Returns the number of rows affected by an insert, update, or delete request. |
| <code>SQLNumResultCols</code> | Yes | ISO 92 | Returns the number of columns in the result set. |
| <code>SQLDescribeCol</code> | Yes | ISO 92 | Describes a column in the result set. |
| <code>SQLColAttribute</code> | Yes | ISO 92 | Describes attributes of a column in the result set. |
| <code>SQLColAttributes</code> | Yes | Deprecated | Describes attributes of a column in the result set. |
| <code>SQLFetch</code> | Yes | ISO 92 | Returns multiple result rows. |
| <code>SQLFetchScroll</code> | Yes | ISO 92 | Returns scrollable result rows. |
| <code>SQLExtendedFetch</code> | Yes | Deprecated | Returns scrollable result rows. |
| <code>SQLSetPos</code> | Yes | ODBC | Positions a cursor within a fetched block of data and enables an application to refresh data in the rowset or to update or delete data in the result set. |
| <code>SQLBulkOperations</code> | Yes | ODBC | Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark. |

Table 22.12. ODBC API Calls for Retrieving Error or Diagnostic Information

| Function Name | Connector/ODBC Supports? | Standard | Purpose |
|------------------------------|--------------------------|------------|---|
| <code>SQLError</code> | Yes | Deprecated | Returns additional error or status information |
| <code>SQLGetDiagField</code> | Yes | ISO 92 | Returns additional diagnostic information (a single field of the diagnostic data structure). |
| <code>SQLGetDiagRec</code> | Yes | ISO 92 | Returns additional diagnostic information (multiple fields of the diagnostic data structure). |

Table 22.13. ODBC API Calls for Obtaining Information about the Data Source's System Tables (Catalog Functions) Item

| Function Name | Connector/ODBC Supports? | Standard | Purpose |
|----------------------------------|--------------------------|----------|---|
| <code>SQLColumnPrivileges</code> | Yes | ODBC | Returns a list of columns and associated privileges for one or more tables. |
| <code>SQLColumns</code> | Yes | X/Open | Returns the list of column names in specified tables. |

| Function Name | Connector/ ODBC Supports? | Standard | Purpose |
|---------------------------------|---------------------------------|----------|--|
| <code>SQLForeignKeys</code> | Yes | ODBC | Returns a list of column names that make up foreign keys, if they exist for a specified table. |
| <code>SQLPrimaryKeys</code> | Yes | ODBC | Returns the list of column names that make up the primary key for a table. |
| <code>SQLSpecialColumns</code> | Yes | X/Open | Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction. |
| <code>SQLStatistics</code> | Yes | ISO 92 | Returns statistics about a single table and the list of indexes associated with the table. |
| <code>SQLTablePrivileges</code> | Yes | ODBC | Returns a list of tables and the privileges associated with each table. |
| <code>SQLTables</code> | Yes | X/Open | Returns the list of table names stored in a specific data source. |

Table 22.14. ODBC API Calls for Performing Transactions

| Function Name | Connector/ ODBC Supports? | Standard | Purpose |
|--------------------------|---------------------------------|------------|---|
| <code>SQLTransact</code> | Yes | Deprecated | Commits or rolls back a transaction |
| <code>SQLEndTran</code> | Yes | ISO 92 | Commits or rolls back a transaction . |

Table 22.15. ODBC API Calls for Terminating a Statement

| Function Name | Connector/ ODBC Supports? | Standard | Purpose |
|-----------------------------|---------------------------------|----------|---|
| <code>SQLFreeStmt</code> | Yes | ISO 92 | Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle. |
| <code>SQLCloseCursor</code> | Yes | ISO 92 | Closes a cursor that has been opened on a statement handle. |
| <code>SQLCancel</code> | Yes | ISO 92 | Cancels an SQL statement. |

Table 22.16. ODBC API Calls for Terminating a Connection

| Function Name | Connector/ ODBC Supports? | Standard | Purpose |
|-----------------------------|---------------------------------|------------|---|
| <code>SQLDisconnect</code> | Yes | ISO 92 | Closes the connection. |
| <code>SQLFreeHandle</code> | Yes | ISO 92 | Releases an environment, connection, statement, or descriptor handle. |
| <code>SQLFreeConnect</code> | Yes | Deprecated | Releases connection handle. |
| <code>SQLFreeEnv</code> | Yes | Deprecated | Releases an environment handle. |

22.1.6.2. Connector/ODBC Data Types

The following table illustrates how Connector/ODBC maps the server data types to default SQL and C data types.

Table 22.17. How Connector/ODBC Maps MySQL Data Types to SQL and C Data Types

| Native Value | SQL Type | C Type |
|---------------------------------|-------------------|-----------------|
| bigint unsigned | SQL_BIGINT | SQL_C_UBIGINT |
| bigint | SQL_BIGINT | SQL_C_SBIGINT |
| bit | SQL_BIT | SQL_C_BIT |
| bit | SQL_CHAR | SQL_C_CHAR |
| blob | SQL_LONGVARBINARY | SQL_C_BINARY |
| bool | SQL_CHAR | SQL_C_CHAR |
| char | SQL_CHAR | SQL_C_CHAR |
| date | SQL_DATE | SQL_C_DATE |
| datetime | SQL_TIMESTAMP | SQL_C_TIMESTAMP |
| decimal | SQL_DECIMAL | SQL_C_CHAR |
| double precision | SQL_DOUBLE | SQL_C_DOUBLE |
| double | SQL_FLOAT | SQL_C_DOUBLE |
| enum | SQL_VARCHAR | SQL_C_CHAR |
| float | SQL_REAL | SQL_C_FLOAT |
| int unsigned | SQL_INTEGER | SQL_C_ULONG |
| int | SQL_INTEGER | SQL_C_SLONG |
| integer unsigned | SQL_INTEGER | SQL_C_ULONG |
| integer | SQL_INTEGER | SQL_C_SLONG |
| long varbinary | SQL_LONGVARBINARY | SQL_C_BINARY |
| long varchar | SQL_LONGVARCHAR | SQL_C_CHAR |
| longblob | SQL_LONGVARBINARY | SQL_C_BINARY |
| longtext | SQL_LONGVARCHAR | SQL_C_CHAR |
| mediumblob | SQL_LONGVARBINARY | SQL_C_BINARY |
| mediumint unsigned | SQL_INTEGER | SQL_C_ULONG |
| mediumint | SQL_INTEGER | SQL_C_SLONG |
| mediumtext | SQL_LONGVARCHAR | SQL_C_CHAR |
| numeric | SQL_NUMERIC | SQL_C_CHAR |
| real | SQL_FLOAT | SQL_C_DOUBLE |
| set | SQL_VARCHAR | SQL_C_CHAR |
| smallint unsigned | SQL_SMALLINT | SQL_C_USHORT |
| smallint | SQL_SMALLINT | SQL_C_SSHORT |
| text | SQL_LONGVARCHAR | SQL_C_CHAR |
| time | SQL_TIME | SQL_C_TIME |
| timestamp [567] | SQL_TIMESTAMP | SQL_C_TIMESTAMP |

| Native Value | SQL Type | C Type |
|-------------------------------|--------------------------------|-----------------------------|
| <code>tinyblob</code> | <code>SQL_LONGVARBINARY</code> | <code>SQL_C_BINARY</code> |
| <code>tinyint unsigned</code> | <code>SQL_TINYINT</code> | <code>SQL_C_UTINYINT</code> |
| <code>tinyint</code> | <code>SQL_TINYINT</code> | <code>SQL_C_STINYINT</code> |
| <code>tinytext</code> | <code>SQL_LONGVARCHAR</code> | <code>SQL_C_CHAR</code> |
| <code>varchar</code> | <code>SQL_VARCHAR</code> | <code>SQL_C_CHAR</code> |
| <code>year</code> | <code>SQL_SMALLINT</code> | <code>SQL_C_SHORT</code> |

22.1.6.3. Connector/ODBC Error Codes

The following tables lists the error codes returned by Connector/ODBC apart from the server errors.

Table 22.18. Special Error Codes Returned by Connector/ODBC

| Native Code | SQLSTATE 2 | SQLSTATE 3 | Error Message |
|-------------|------------|------------|---|
| 500 | 01000 | 01000 | General warning |
| 501 | 01004 | 01004 | String data, right truncated |
| 502 | 01S02 | 01S02 | Option value changed |
| 503 | 01S03 | 01S03 | No rows updated/deleted |
| 504 | 01S04 | 01S04 | More than one row updated/deleted |
| 505 | 01S06 | 01S06 | Attempt to fetch before the result set returned the first row set |
| 506 | 07001 | 07002 | <code>SQLBindParameter</code> not used for all parameters |
| 507 | 07005 | 07005 | Prepared statement not a cursor-specification |
| 508 | 07009 | 07009 | Invalid descriptor index |
| 509 | 08002 | 08002 | Connection name in use |
| 510 | 08003 | 08003 | Connection does not exist |
| 511 | 24000 | 24000 | Invalid cursor state |
| 512 | 25000 | 25000 | Invalid transaction state |
| 513 | 25S01 | 25S01 | Transaction state unknown |
| 514 | 34000 | 34000 | Invalid cursor name |
| 515 | S1000 | HY000 | General driver defined error |
| 516 | S1001 | HY001 | Memory allocation error |
| 517 | S1002 | HY002 | Invalid column number |
| 518 | S1003 | HY003 | Invalid application buffer type |
| 519 | S1004 | HY004 | Invalid SQL data type |
| 520 | S1009 | HY009 | Invalid use of null pointer |
| 521 | S1010 | HY010 | Function sequence error |
| 522 | S1011 | HY011 | Attribute can not be set now |
| 523 | S1012 | HY012 | Invalid transaction operation code |
| 524 | S1013 | HY013 | Memory management error |

| Native Code | SQLSTATE 2 | SQLSTATE 3 | Error Message |
|-------------|------------|------------|---|
| 525 | S1015 | HY015 | No cursor name available |
| 526 | S1024 | HY024 | Invalid attribute value |
| 527 | S1090 | HY090 | Invalid string or buffer length |
| 528 | S1091 | HY091 | Invalid descriptor field identifier |
| 529 | S1092 | HY092 | Invalid attribute/option identifier |
| 530 | S1093 | HY093 | Invalid parameter number |
| 531 | S1095 | HY095 | Function type out of range |
| 532 | S1106 | HY106 | Fetch type out of range |
| 533 | S1117 | HY117 | Row value out of range |
| 534 | S1109 | HY109 | Invalid cursor position |
| 535 | S1C00 | HYC00 | Optional feature not implemented |
| 0 | 21S01 | 21S01 | Column count does not match value count |
| 0 | 23000 | 23000 | Integrity constraint violation |
| 0 | 42000 | 42000 | Syntax error or access violation |
| 0 | 42S02 | 42S02 | Base table or view not found |
| 0 | 42S12 | 42S12 | Index not found |
| 0 | 42S21 | 42S21 | Column already exists |
| 0 | 42S22 | 42S22 | Column not found |
| 0 | 08S01 | 08S01 | Communication link failure |

22.1.7. Connector/ODBC Notes and Tips

Here are some common notes and tips for using Connector/ODBC within different environments, applications and tools. The notes provided here are based on the experiences of Connector/ODBC developers and users.

22.1.7.1. Connector/ODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with Connector/ODBC.

22.1.7.1.1. Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` [1194] function.

For example, using Connector/ODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');  
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

This alternative method requires that `sql_auto_is_null` [554] variable is not set to 0. See [Section 5.1.4, “Server System Variables”](#).

See also [Section 22.8.11.3, “How to Get the Unique ID for the Last Inserted Row”](#).

22.1.7.1.2. Dynamic Cursor Support

Support for the `dynamic cursor` is provided in Connector/ODBC 3.51, but dynamic cursors are not enabled by default. You can enable this function within Windows by selecting the `Enable Dynamic Cursor` check box within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding `32` to the `OPTION` value when creating the DSN.

22.1.7.1.3. Connector/ODBC Performance

The Connector/ODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of Connector/ODBC, or notice a large amount of disk activity for simple queries, there are a number of aspects to check:

- Ensure that `ODBC Tracing` is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the `Tracing` panel of the ODBC Data Source Administrator. Within Mac OS X, check the `Tracing` panel of ODBC Administrator. See [Section 22.1.4.8, “Getting an ODBC Trace File”](#).
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.
- Disable the Connector/ODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the Connector/ODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

22.1.7.1.4. Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

22.1.7.2. Connector/ODBC Application-Specific Tips

Most programs should work with Connector/ODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with Connector/ODBC and these applications.

With all applications, ensure that you are using the latest Connector/ODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the Connector/ODBC driver.

22.1.7.2.1. Using Connector/ODBC with Microsoft Applications

The majority of Microsoft applications have been tested with Connector/ODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

22.1.7.2.1.1. Microsoft Access

To improve the integration between Microsoft Access and MySQL through Connector/ODBC:

- For all versions of Access, enable the Connector/ODBC `Return matching rows` option. For Access 2.0, also enable the `Simulate ODBC 1.0` option.
- Include a `TIMESTAMP` column in all tables that you want to be able to update. For maximum portability, do not use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- Include a `primary key` in each MySQL table you want to use with Access. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
 - Have one more dummy column with `TIMESTAMP` as the data type.
 - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
 - Delete the table link from Access and re-create it.

Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.

- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

Do not use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. Set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()` [1143]. Consider hiding the `TIMESTAMP` column from view so your users are not confused.

- In some cases, Access may generate SQL statements that MySQL cannot understand. You can fix this by selecting `"Query | SQLSpecific | Pass-Through"` from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, change `BLOB` columns to `TEXT` with `ALTER TABLE`.
- Access cannot always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:

- Return Matching Rows (2)
- Allow BIG Results (8).

These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and Connector/ODBC:

- Read [How to Trap ODBC Login Error Messages in Access](#)
- Optimizing Access ODBC Applications
 - [Optimizing for Client/Server Performance](#)
 - [Tips for Converting Applications to Using ODBCDirect](#)
 - [Tips for Optimizing Queries on Attached SQL Tables](#)
- For a list of tools that can be used with Access and ODBC data sources, refer to <http://www.mysql.com/portal/software/convertors/> section for list of available tools.

22.1.7.2.1.2. Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numeric, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT () [1102]` function in your queries. The use of `CONCAT () [1102]` forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the `Format Cells` option within Excel to change the format of the displayed information.

22.1.7.2.1.3. Microsoft Visual Basic

To be able to update a table, you must define a `primary key` for the table.

Visual Basic with ADO cannot handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen. You may also want to select the `Return matching rows` option.

22.1.7.2.1.4. Microsoft Visual InterDev

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen.

22.1.7.2.1.5. Visual Objects

Select the `Don't optimize column widths` option.

22.1.7.2.1.6. Microsoft ADO

When you are coding with the ADO API and Connector/ODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the [CursorLocation Property](#) as `adUseServer` returns a result of `-1` for the [RecordCount Property](#). To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the [RecordsAffected](#) property in the ADO execute method. For more information on the usage of execute method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnnextecute.asp>.

For information, see [ActiveX Data Objects\(ADO\) Frequently Asked Questions](#).

22.1.7.2.1.7. Using Connector/ODBC with Active Server Pages (ASP)

Select the [Return matching rows](#) option in the DSN.

For more information about how to access MySQL through ASP using Connector/ODBC, refer to the following articles:

- [Using MyODBC To Access Your MySQL Database Via ASP](#)
- [ASP and MySQL at DWAM.NT](#)

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

22.1.7.2.1.8. Using Connector/ODBC with Visual Basic (ADO, DAO and RDO) and ASP

Some articles that may help with Visual Basic and ASP:

- [MySQL BLOB columns and Visual Basic 6](#) by Mike Hillyer (<mike@openwin.org>).
- [How to map Visual basic data type to MySQL types](#) by Mike Hillyer (<mike@openwin.org>).

22.1.7.2.2. Using Connector/ODBC with Borland Applications

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.
- Enable the [Don't optimize column widths](#) option in the DSN.

- Enabled the [Return matching rows](#) option in the DSN.

22.1.7.2.2.1. Using Connector/ODBC with Borland Builder 4

When you start a query, you can use the [Active](#) property or the [Open](#) method. Note that [Active](#) starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

22.1.7.2.2.2. Using Connector/ODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for Connector/ODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', ' ');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', ' ');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memo1.Lines.Add('DATABASE NAME=');
Memo1.Lines.Add('USER NAME=');
Memo1.Lines.Add('ODBC DSN=DocumentsFab');
Memo1.Lines.Add('OPEN MODE=READ/WRITE');
Memo1.Lines.Add('BATCH COUNT=200');
Memo1.Lines.Add('LANGDRIVER=');
Memo1.Lines.Add('MAX ROWS=-1');
Memo1.Lines.Add('SCHEMA CACHE DIR=');
Memo1.Lines.Add('SCHEMA CACHE SIZE=8');
Memo1.Lines.Add('SCHEMA CACHE TIME=-1');
Memo1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memo1.Lines.Add('SQLQRYMODE=');
Memo1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memo1.Lines.Add('ENABLE BCD=FALSE');
Memo1.Lines.Add('ROWSET SIZE=20');
Memo1.Lines.Add('BLOBS TO CACHE=64');
Memo1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab', 'MySQL', Memo1.Lines);
```

22.1.7.2.2.3. Using Connector/ODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named [PRIMARY](#), although this has not been a problem.

22.1.7.2.3. Using Connector/ODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the [unixODBC](#) driver with Connector/ODBC for MySQL data sources. You can download Connector/ODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion version 4.5.1 lets you use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC data sources drop-down list, build and copy the Connector/ODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The Contrib directory contains the program `mydsn-xxx.zip` which lets you build and remove the DSN registry file for the Connector/ODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and Connector/ODBC, see the following external sites:

- [Troubleshooting Data Sources and Database Connectivity for Unix Platforms](#).

22.1.7.2.4. Using Connector/ODBC with OpenOffice.org

Open Office (<http://www.openoffice.org>) [How-to: MySQL + OpenOffice](#). [How-to: OpenOffice + MyODBC + unixODBC](#).

22.1.7.2.5. Using Connector/ODBC with Sambar Server

Sambar Server (<http://www.sambarserver.info>) [How-to: MyODBC + SambarServer + MySQL](#).

22.1.7.2.6. Using Connector/ODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

22.1.7.2.7. Using Connector/ODBC with SunSystems Vision

Select the `Return matching rows` option.

22.1.7.3. Connector/ODBC Errors and Resolutions (FAQ)

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the Connector/ODBC mailing list; see [Section 22.1.8.1, "Connector/ODBC Community Support"](#).

Many problems can be resolved by upgrading your Connector/ODBC drivers to the latest available release. On Windows, make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

64-Bit Windows and ODBC Data Source Administrator

I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in [ODBC Data Source Administrator](#).

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the Connector/ODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default [ODBC Data Source Administrator](#) that is available through the [Administrative Tools](#) or [Control Panel](#) in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed Connector/ODBC drivers and enable you to create a Connector/ODBC DSN.

This issue was originally reported as Bug #20301.

Error 10061 (Cannot connect to server)

When connecting or using the **Test** button in [ODBC Data Source Administrator](#) I get error 10061 (Cannot connect to server)

This error can be raised by a number of different issues, including server problems, network problems, and firewall and port blocking problems. For more information, see [Section C.5.2.2, "Can't connect to \[local\] MySQL server"](#).

"Transactions are not enabled" Error

The following error is reported when using transactions: `Transactions are not enabled`

This error indicates that you are trying to use [transactions](#) with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the [InnoDB](#) database engine, which is the default storage engine in MySQL 5.5 and higher. In versions of MySQL before MySQL 5.1, you may also use the [BDB](#) engine.

Check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use [SHOW ENGINES](#) to obtain a list of the available engine types.
- Verify that the tables you are updating use a transactional database engine.
- Ensure that you have not enabled the [disable transactions](#) option in your DSN.

#DELETED# Records Reported by Access

Access reports records as `#DELETED#` when inserting or updating records in linked tables.

If the inserted or updated records are shown as `#DELETED#` in Access, then:

- If you are using Access 2000, get and install the newest (version 2.6 or higher) Microsoft MDAC ([Microsoft Data Access Components](#)) from <http://support.microsoft.com/kb/110093>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified.

Also, get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5), which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as `#DELETED#` in Access.
- For all versions of Access, enable the Connector/ODBC [Return matching rows](#) option. For Access 2.0, also enable the [Simulate ODBC 1.0](#) option.
- Include a [TIMESTAMP](#) in all tables that you want to be able to update.
- Include a [primary key](#) in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only [DOUBLE](#) float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a [BIGINT](#) column, the results are displayed as `#DELETED`. The work around solution is:
 - Have one more dummy column with [TIMESTAMP](#) as the data type.
 - Select the [Change BIGINT columns to INT](#) option in the connection dialog in ODBC DSN Administrator.

- Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

Write Conflicts or Row Location Errors

How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the [Return Matching Rows](#) option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.  
  
Row cannot be located for updating. Some values may have been changed  
since it was last read.
```

Importing from Access 97

Exporting data from Access 97 to MySQL reports a [Syntax Error](#).

This error is specific to Access 97 and versions of Connector/ODBC earlier than 3.51.02. Update to the latest version of the Connector/ODBC driver to resolve this problem.

Importing from Microsoft DTS

Exporting data from Microsoft DTS to MySQL reports a [Syntax Error](#).

This error occurs only with MySQL tables using the [TEXT](#) or [VARCHAR](#) data types. You can fix this error by upgrading your Connector/ODBC driver to version 3.51.02 or higher.

SQL_NO_DATA Exception from ODBC.NET

Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the [SQL_NO_DATA](#) exception.

You can get the patch that addresses this problem from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

Error with SELECT COUNT(*)

Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.

This error occurs because the `COUNT(*) [1204]` expression is returning a [BIGINT](#), and ADO cannot make sense of a number this big. Select the [Change BIGINT columns to INT](#) option (option value 16384).

Multiple-Step Operation Error

Using the `AppendChunk()` or `GetChunk()` ADO methods, the [Multiple-step operation generated errors. Check each status value](#) error is returned.

The `GetChunk()` and `AppendChunk()` methods from ADO do not work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm

Modified Record Error

Access returns [Another user had modified the record that you have modified while editing records on a Linked Table](#).

In most cases, this can be solved by doing one of the following things:

- Add a [primary key](#) for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies do not help, start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a Connector/ODBC log to help you figure out why things go wrong. For instructions, see [Section 22.1.4.8, "Getting an ODBC Trace File"](#).

Direct Application Linking Under Unix or Linux

When linking an application directly to the Connector/ODBC library under Unix or Linux, the application crashes.

Connector/ODBC under Unix or Linux is not compatible with direct application linking. To connect to an ODBC source, use a driver manager, such as [iODBC](#) or [unixODBC](#).

Microsoft Office and DATE or TIMESTAMP Columns

Applications in the Microsoft Office suite cannot update tables that have [DATE](#) or [TIMESTAMP](#) columns.

This is a known issue with Connector/ODBC. Ensure that the field has a default value (rather than [NULL](#)) and that the default value is nonzero (that is, something other than [0000-00-00 00:00:00](#)).

INFORMATION_SCHEMA Database

When connecting Connector/ODBC 5.x to a MySQL 4.x server, the error [1044 Access denied for user 'xxx'@'%' to database 'information_schema'](#) is returned.

Connector/ODBC 5.x is designed to work with MySQL 5.0 or later, taking advantage of the [INFORMATION_SCHEMA](#) database to determine data definition information. Support for MySQL 4.1 is planned for the final release.

S1T00 Error

When calling [SQLTables](#), the error [S1T00](#) is returned, but I cannot find this in the list of error numbers for Connector/ODBC.

The [S1T00](#) error indicates that a general timeout has occurred within the ODBC system and is not a MySQL error. Typically it indicates that the connection you are using is stale, the server is too busy to accept your request or that the server has gone away.

"Table does not exist" Error in Access 2000

When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.

There is a known issue with a specific version of the [msjet40.dll](#) that exhibits this issue. The version affected is 4.0.9025.0. Reverting to an older version will enable you to create the links. If you have recently updated your version, check your [WINDOWS](#) directory for the older version of the file and copy it to the drivers directory.

Batched Statements

When I try to use batched statements, the execution of the batched statements fails.

Batched statement support was added in 3.51.18. Support for batched statements is not enabled by default. Enable option `FLAG_MULTI_STATEMENTS`, value 67108864, or select the **Allow multiple statements** flag within a GUI configuration.

Packet Errors with ADODB and Excel

When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.

This error may be related to Keyboard Logger 1.1 from PanteraSoft.com, which is known to interfere with the network communication between MySQL Connector/ODBC and MySQL.

Outer Join Error

When using some applications to access a MySQL server using Connector/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.

This is a known issue with MySQL Connector/ODBC which is not correctly parsing the "Outer Join Escape Sequence", as per the specs at [Microsoft ODBC Specs](#). Currently, Connector/ODBC will return a value > 0 when asked for `SQL_OJ_CAPABILITIES` even though no parsing takes place in the driver to handle the outer join escape sequence.

Hebrew/CJK Characters

I can correctly store extended characters in the database (Hebrew/CJK) using Connector/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.

When using ASP and UTF8 characters, add the following to your ASP files to ensure that the data returned is correctly encoded:

```
Response.CodePage = 65001
Response.CharSet = "utf-8"
```

Duplicate Entry in Installed Programs List

I have a duplicate MySQL Connector/ODBC entry within my **Installed Programs** list, but I cannot delete one of them.

This problem can occur when you upgrade an existing Connector/ODBC installation, rather than removing and then installing the updated version.

Warning

To fix the problem, use any working uninstallers to remove existing installations; then may have to edit the contents of the registry. Make sure you have a backup of your registry information before attempting any editing of the registry contents.

Values Truncated to 255 Characters

When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.

Ensure that the `FLAG_BIG_PACKETS` option is set for your connection. This removes the 255 character limitation on bound parameters.

Disabling Data-At-Execution

Is it possible to disable data-at-execution using a flag?

If you do not want to use data-at-execution, remove the corresponding calls. For example:

```
SQLLEN ylen = SQL_LEN_DATA_AT_EXEC(10);
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, &ylen);
```

Would become:

```
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, NULL);
```

Note that in the call to `SQLBindCol()`, `&ylen` has been replaced by `NULL`.

For further information, refer to the [MSDN documentation](#) for `SQLBindCol()`.

NULLABLE Attribute for AUTO_INCREMENT Columns

When you call `SQLColumns()` for a table column that is `AUTO_INCREMENT`, the `NULLABLE` column of the result set is always `SQL_NULLABLE (1)`.

This is because MySQL reports the `DEFAULT` value for such a column as `NULL`. It means, if you insert a `NULL` value into the column, you will get the next integer value for the table's `auto_increment` counter.

22.1.8. Connector/ODBC Support

There are many different places where you can get support for using Connector/ODBC. Always try the Connector/ODBC Mailing List or Connector/ODBC Forum. See [Section 22.1.8.1, “Connector/ODBC Community Support”](#), for help before reporting a specific bug or issue to MySQL.

22.1.8.1. Connector/ODBC Community Support

Oracle provides assistance to the user community by means of its mailing lists. For Connector/ODBC-related issues, you can get help from experienced users by using the `<myodbc@lists.mysql.com>` mailing list. Archives are available online at <http://lists.mysql.com/myodbc>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, “MySQL Mailing Lists”](#).

Community support from experienced users is also available through the [ODBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, “MySQL Community Support at the MySQL Forums”](#).

22.1.8.2. How to Report Connector/ODBC Problems or Bugs

If you encounter difficulties or problems with Connector/ODBC, start by making a log file from the [ODBC Manager](#) (the log you get when requesting logs from `ODBC ADMIN`) and Connector/ODBC. The procedure for doing this is described in [Section 22.1.4.8, “Getting an ODBC Trace File”](#).

Check the Connector/ODBC trace file to find out what could be wrong. Determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

Also, try issuing the statements from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/ODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#). Please never send the whole Connector/ODBC or ODBC log file!

Ideally, include the following information with the email:

- Operating system and version
- Connector/ODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- Connector/ODBC log file from Connector/ODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/myodbc>.

If you are unable to find out what is wrong, the last option is to create an archive in `tar` or `zip` format that contains a Connector/ODBC trace file, the ODBC log file, and a `README` file that explains the problem. Initiate a bug report for our bugs database at <http://bugs.mysql.com/>, then click the Files tab in the bug report for instructions on uploading the archive to the bugs database. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

22.1.8.3. How to Submit a Connector/ODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com).

22.2. MySQL Connector/Net

Connector/Net lets you easily develop .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET-aware tools. Developers can build applications using their choice of .NET languages. Connector/Net is a fully managed ADO.NET driver written in 100% pure C#.

Connector/Net includes full support for:

- Features provided by MySQL Server up to and including MySQL Server version 5.5.
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.
- Protocol compression, which enables compressing the data stream between the client and server.
- Connections using TCP/IP sockets, named pipes, or shared memory on Windows.
- Connections using TCP/IP sockets or Unix sockets on Unix.
- The Open Source Mono framework developed by Novell.

- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/Net and includes a full syntax reference. Syntax information is also included within the [Documentation.chm](#) file included with the Connector/Net distribution.

If you are using MySQL 5.0 or later, and Visual Studio as your development environment, you can also use the MySQL Visual Studio Plugin. The plugin acts as a DDEX (Data Designer Extensibility) provider: you can use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For more information, see [Section 22.2.3, "Connector/Net Visual Studio Integration"](#).

Note

Connector/Net 5.1.2 and later include the Visual Studio Plugin by default.

MySQL Connector/Net supports full versions of Visual Studio 2005, 2008, and 2010, although certain features are only available in Visual Studio 2010 when using MySQL Connector/Net version 6.3.2 and later. Note that MySQL Connector/Net does not currently support Express versions of Microsoft products, including Microsoft Visual Web Developer.

Key topics:

- For connection string properties when using the `MySqlConnection` class, see [Section 22.2.6, "Connector/Net Connection String Options Reference"](#).

For release notes detailing the changes in each release of Connector/Net, see [MySQL Connector/Net Release Notes](#).

As of Connector/Net 5.1.2, the Visual Studio Plugin is part of the main Connector/Net package. However, even for versions of Connector/Net older than 5.1.2, the Visual Studio Plugin release notes can be found at [MySQL Connector/Net Release Notes](#).

22.2.1. Connector/Net Versions

There are several versions of Connector/Net available:

- Connector/Net 6.6 includes support for MySQL Server 5.6, 5.5, 5.1, and 5.0. Important new features include stored procedure debugging in Microsoft Visual Studio, support for pluggable authentication including the ability to write your own authentication plugin, Entity Framework 4.3 Code First support, and enhancements to partial trust support to allow hosting services to deploy applications without installing the Connector/Net library in the GAC.
- Connector/Net 6.5 includes support for MySQL Server 5.6, 5.5, 5.1, and 5.0. Important new features include interceptor classes for exceptions and commands, support for the MySQL 5.6 fractional seconds feature, better partial-trust support, and better IntelliSense, including auto-completion when editing stored procedures or `.mysql` files.
- Connector/Net 6.4 includes support for MySQL Server 5.5, 5.1, and 5.0. Important new features include support for Windows authentication (when connecting to MySQL Server 5.5+), table caching on the client side, simple connection fail-over support, and improved SQL generation from the Entity Framework provider.
- Connector/Net 6.3 includes support for MySQL Server 5.5, 5.1, and 5.0. Important new features include integration with Visual Studio 2010, such as availability of DDL T4 template for Entity Framework, and a custom MySQL SQL Editor. Other features include refactored transaction scope: Connector/Net now supports nested transactions in a scope where they use the same connection string.

- Connector/Net 6.2 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1. Important new features include a new logging system and client SSL certificates.
- Connector/Net 6.1 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1. Important new features include the MySQL Website Configuration Tool and a Session State Provider.
- Connector/Net 6.0 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1.

This version of Connector/Net is no longer supported.

- Connector/Net 5.2 includes support for MySQL Server 5.5, 5.1, 5.0, and 4.1 features. Connector/Net 5.2 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to [GetSchema](#). Connector/Net 5.2 also includes the Visual Studio Plugin as a standard installable component.

This version of Connector/Net is no longer supported.

- Connector/Net 5.1 includes support for MySQL Server 5.5, 5.1, 5.0, 4.1, and 4.0 features. Connector/Net 5.1 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to [GetSchema](#). Connector/Net 5.1 also includes the Visual Studio Plugin as a standard installable component.

This version of Connector/Net is no longer supported.

- Connector/Net 5.0 includes support for MySQL Server 5.1, 5.0, 4.1 and 4.0 features. Connector/Net 5.0 also includes full support for the ADO.NET 2.0 interfaces and subclasses, includes support for the usage advisor and performance monitor (PerfMon) hooks.

This version of Connector/Net is no longer supported.

- Connector/Net 1.0 includes support for MySQL Server 5.0, 4.1, and 4.0 features, and full compatibility with the ADO.NET driver interface.

This version of Connector/Net is no longer supported.

The latest source code for Connector/Net can be downloaded from the MySQL public Subversion server. For further details, see [Section 22.2.2.3, "Installing Connector/Net from the Source Code"](#).

The following table shows the .NET Framework version required, and the MySQL Server version supported by Connector/Net:

Table 22.19. Connector/Net Requirements for Related Products

| Connector/Net version | ADO.NET version supported | .NET Framework version required | MySQL Server version supported | Currently supported |
|-----------------------|---------------------------|---------------------------------|--------------------------------|---------------------|
| 6.6 | 2.x+ | 2.x+, 4.x+ for VS 2010 support | 5.6, 5.5, 5.1, 5.0 | Yes |
| 6.5 | 2.x+ | 2.x+, 4.x+ for VS 2010 support | 5.6, 5.5, 5.1, 5.0 | Yes |
| 6.4 | 2.x+ | 2.x+, 4.x+ for VS 2010 support | 5.6, 5.5, 5.1, 5.0 | Yes |
| 6.3 | 2.x+ | 2.x+, 4.x+ for VS 2010 support | 5.6, 5.5, 5.1, 5.0 | Yes |
| 6.2 | 2.x+ | 2.x+ | 5.6, 5.5, 5.1, 5.0, 4.1 | Yes |

| Connector/Net version | ADO.NET version supported | .NET Framework version required | MySQL Server version supported | Currently supported |
|-----------------------|---------------------------|---------------------------------|--------------------------------|----------------------|
| 6.1 | 2.x+ | 2.x+ | 5.6, 5.5, 5.1, 5.0, 4.1 | Yes |
| 6.0 | 2.x+ | 2.x+ | 5.5, 5.1, 5.0, 4.1 | Critical issues only |
| 5.2 | 2.x+ | 2.x+ | 5.5, 5.1, 5.0, 4.1 | No |
| 5.1 | 2.x+ | 2.x+ | 5.5, 5.1, 5.0, 4.1, 4.0 | No |
| 5.0 | 2.x+ | 2.x+ | 5.0, 4.1, 4.0 | No |
| 1.0 | 1.x | 1.x | 5.0, 4.1, 4.0 | No |

Note

Version numbers for MySQL products are formatted as X.Y.Z, where Z=0 indicates alpha, Z=1 indicates beta, and Z>=2 indicates GA. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.YY.ZZ. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

22.2.2. Installing Connector/Net

Connector/Net runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see <http://www.mono-project.com>).

Connector/Net is available for download from <http://dev.mysql.com/downloads/connector/net/>.

22.2.2.1. Installing Connector/Net on Windows

On Windows, you can install either through a binary installation process or by downloading a zip file with the Connector/Net components.

Before installing, ensure that your system is up to date, including installing the latest version of the .NET Framework.

22.2.2.1.1. Installing Connector/Net using the Installer

Using the installer is the most straightforward method of installing Connector/Net on Windows and the installed components include the source code, test code and full reference documentation.

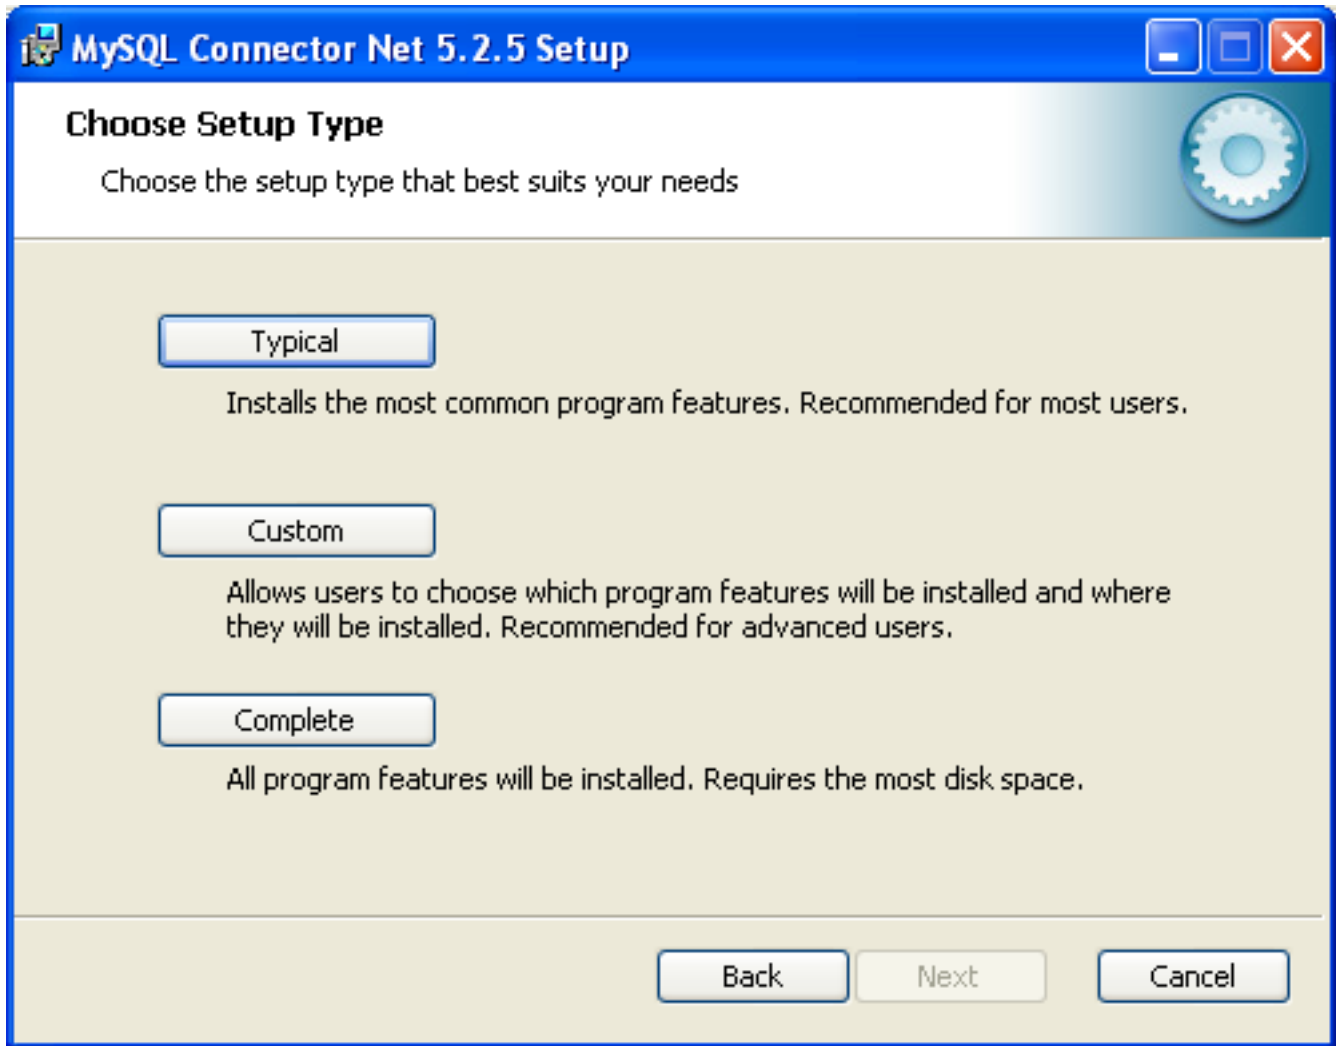

You install Connector/Net through a Windows Installer (.msi) installation package, which can install Connector/Net on all Windows operating systems. The MSI package is contained within a zip archive named `mysql-connector-net-version.zip`, where `version` indicates the Connector/Net version.

To install Connector/Net:

1. Double-click the MSI installer file extracted from the zip you downloaded. Click **Next** to start the installation.

2. You must choose the type of installation to perform.

For most situations, the Typical installation is suitable. Click the **Typical** button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the **Complete** button and proceed to step 5. To customize your installation, including choosing the components to install and some installation options, click the **Custom** button and proceed to Step 3.

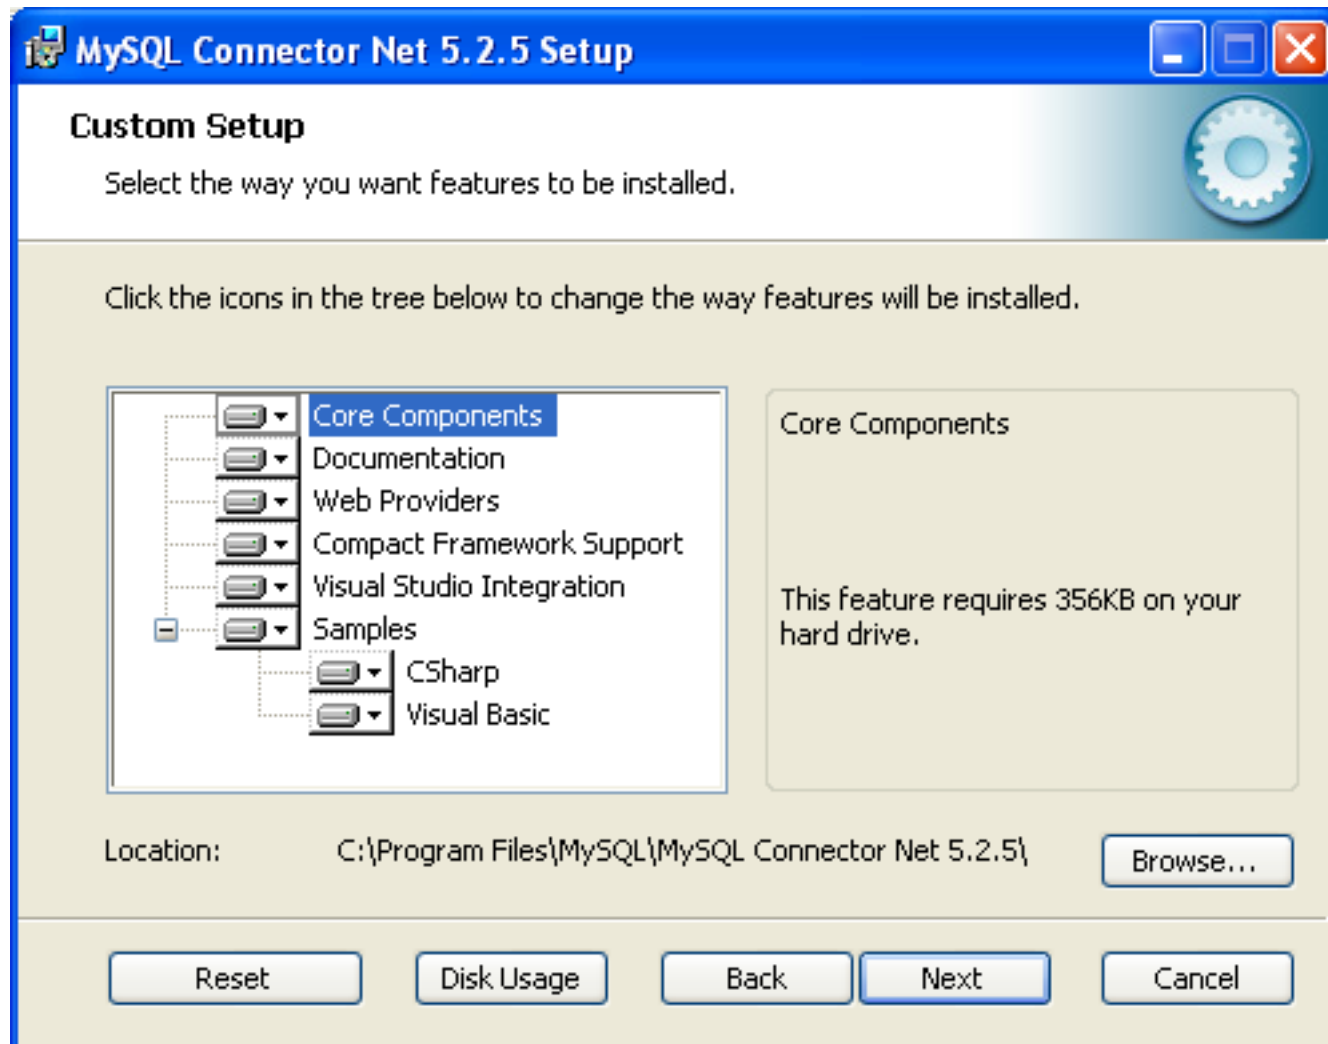

The Connector/Net installer will register the connector within the Global Assembly Cache (GAC) - this will make the Connector/Net component available to all applications, not just those where you explicitly reference the Connector/Net component. The installer will also create the necessary links in the Start menu to the documentation and release notes.

3. If you have chosen a custom installation, you can select the individual components to install, including the core interface component, supporting documentation (a CHM file) samples and examples, and the source code. Select the items, and their installation level, and then click **Next** to continue the installation.

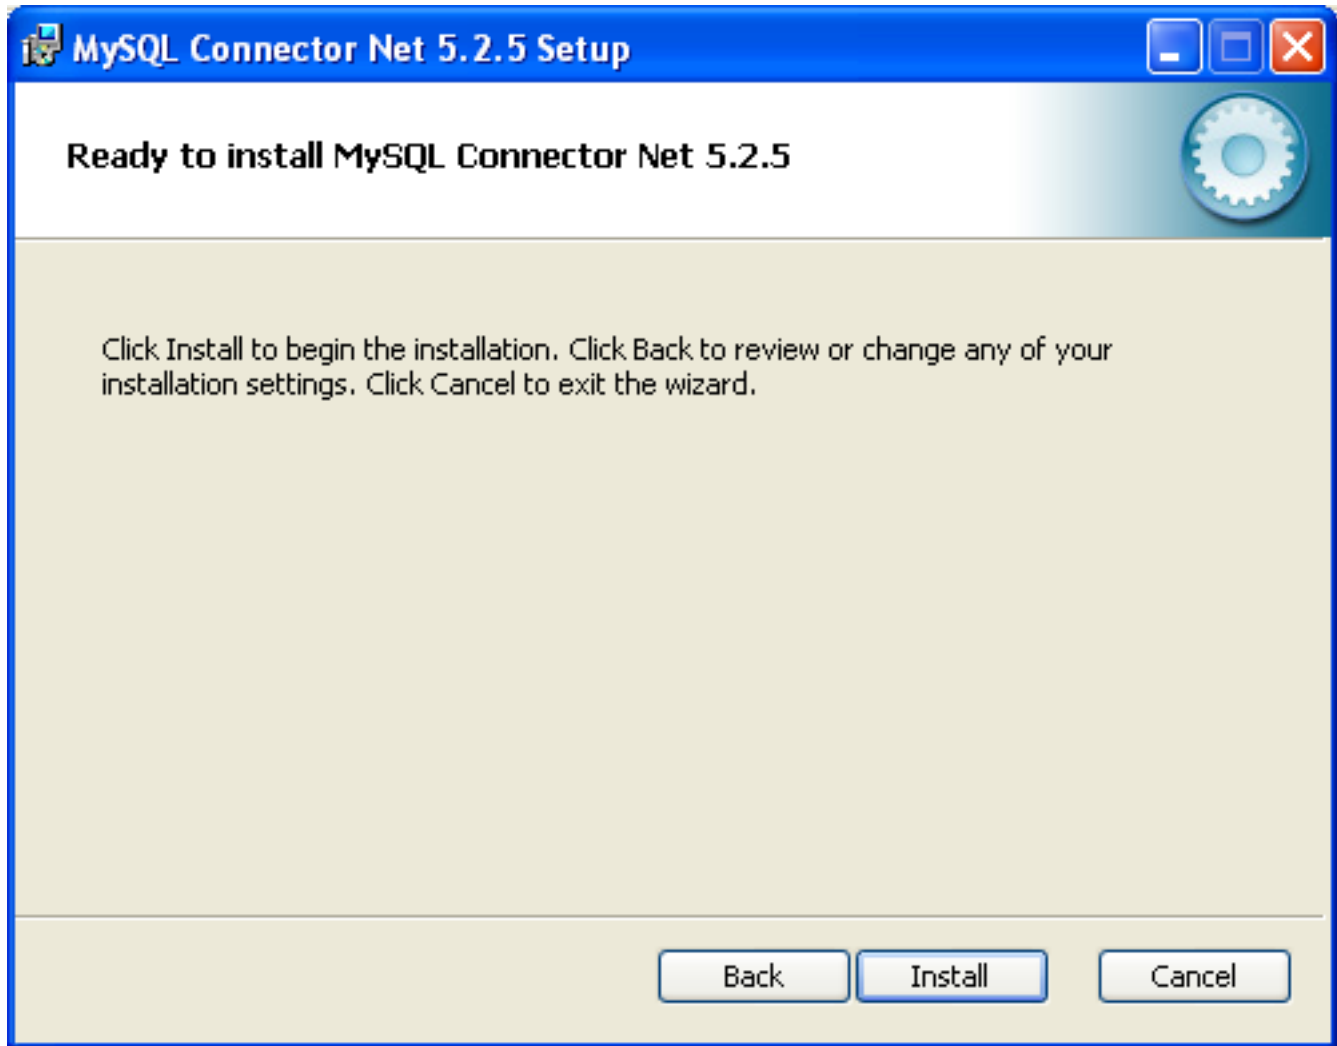

**Note**

For Connector/Net 1.0.8 or lower and Connector 5.0.4 and lower the installer will attempt to install binaries for both 1.x and 2.x of the .NET Framework. If you only have one version of the framework installed, the connector installation

may fail. If this happens, you can choose the framework version to be installed through the custom installation step.

4. You will be given a final opportunity to confirm the installation. Click **Install** to copy and install the files onto your machine.

5. Once the installation has been completed, click **Finish** to exit the installer.

Unless you choose otherwise, Connector/Net is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of Connector/Net you are installing. New installations do not overwrite existing versions of Connector/Net.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin`: Connector/Net MySQL libraries for different versions of the .NET environment.
- `docs`: Connector/Net documentation in CHM format.
- `samples`: Sample code and applications that use the Connector/Net component.
- `src`: The source code for the Connector/Net component.

You may also use the `/quiet` or `/q` command-line option with the `msiexec` tool to install the Connector/Net package automatically (using the default options) with no notification to the user. Using this method the user cannot select options. Additionally, no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package connector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, use the `/passive` option.

22.2.2.1.2. Installing Connector/Net Using the Zip Packages

If you have problems running the installer, you can download a zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. After downloading the zip archive, extract the files to a location of your choice.

The file contains the following directories:

- `bin`: Connector/Net MySQL libraries for different versions of the .NET environment.
- `Docs`: Connector/Net documentation in CHM format.
- `Samples`: Sample code and applications that use the Connector/Net component.

Connector/Net 6.0.x has a different directory structure:

- `Assemblies`: A collection of DLLs that make up the connector functionality.
- `Documentation`: Connector/Net documentation in CHM format.
- `Samples`: sample code and applications that use the Connector/Net component.

Another zip file available for download contains the source code distribution. This file is named `mysql-connector-net-version-src.zip`.

The file contains the following directories:

- `Documentation`: Source files to build the documentation into the compiled HTML (CHM) format.
- `Installer`: Source files to build the Connector/Net installer program.
- `MySQL.Data`: Source files for the core data provider.
- `MySQL.VisualStudio`: Source files for the Microsoft Visual Studio extensions.
- `MySQL.Web`: Source files for the web providers. This includes code for the membership provider, role provider and profile provider. These are used in ASP.NET web sites.
- `Samples`: Source files for several example applications.
- `Tests`: A spreadsheet listing test cases.
- `VisualStudio`: Resources used by the Visual Studio plugin.

Finally, ensure that `MySQL.Data.dll` is accessible to your program at build time (and run time). If using Microsoft Visual Studio, add `MySQL.Data` as a Reference to your project.

Note

If using MySQL Connector/Net 6.3.5 and above, the `MySQL.Data.dll` file provided will work with both .NET Framework 2.x and 4.x.

22.2.2.2. Installing Connector/Net on Unix with Mono

There is no installer available for installing the Connector/Net component on your Unix installation. Before installing, ensure that you have a working Mono project installation. To test whether your system has Mono installed, enter:

```
shell> mono --version
```

The version of the Mono JIT compiler is displayed.

To compile C# source code, make sure a Mono C# compiler is installed. Note that there are two Mono C# compilers available, `mcs`, which accesses the 1.0-profile libraries, and `gmcs`, which accesses the 2.0-profile libraries.

To install Connector/Net on Unix/Mono:

1. Download the `mysql-connector-net-version-noinstall.zip` and extract the contents to a directory of your choice, for example: `~/connector-net/`.
2. In the directory where you unzipped the connector to, change into the `bin` subdirectory. Ensure the file `MySql.Data.dll` is present. This filename is case-sensitive.
3. You must register the Connector/Net component, `MySql.Data`, in the Global Assembly Cache (GAC). In the current directory enter the `gacutil` command:

```
root-shell> gacutil /i MySql.Data.dll
```

This will register `MySql.Data` into the GAC. You can check this by listing the contents of `/usr/lib/mono/gac`, where you will find `MySql.Data` if the registration has been successful.

You are now ready to compile your application. You must ensure that when you compile your application you include the Connector/Net component using the `-r:` command-line option. For example:

```
shell> gmcs -r:System.dll -r:System.Data.dll -r:MySql.Data.dll HelloWorld.cs
```

Note, the assemblies that are referenced depend on the requirements of the application, but applications using Connector/Net must provide `-r:MySql.Data` as a minimum.

You can further check your installation by running the compiled program, for example:

```
shell> mono HelloWorld.exe
```

22.2.2.3. Installing Connector/Net from the Source Code

Caution

Read this section only if you are interested in helping us test our new code. If you just want to get Connector/Net up and running on your system, use a standard release distribution.

Obtaining the Source Code

To obtain the most recent development source tree, first download and install Bazaar. You can obtain Bazaar from the [Bazaar VCS Website](#). Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To check out the Connector/Net sources, change to the directory where you want the copy of the Connector/Net tree to be stored, then use the following command:

```
shell> bzz branch lp:connectornet/trunk
```

To download a specific version of Connector/Net, specify the version number instead of `trunk`. For example, to obtain a copy of the 6.0 version of the source tree:

```
shell> bzz branch lp:connectornet/6.0
```

Source packages are also available on the [downloads page](#).

Building the Source Code on Windows

The following procedure can be used to build the connector on Microsoft Windows.

- Obtain the source code, either from the Subversion server, or through one of the prepared source code packages.
- Navigate to the root of the source code tree.
- A Microsoft Visual Studio 2005 solution file is available to build the connector, this is called `MySQL-VS2005.sln`. Click this file to load the solution into Visual Studio.
- Select **Build**, **Build Solution** from the main menu to build the solution.

Building the Source Code on Unix

Support for building Connector/Net on Mono/Unix is currently not available.

22.2.3. Connector/Net Visual Studio Integration

When MySQL Connector/Net is installed on Microsoft Windows, Visual Studio integration components are also installed and initialized. This enables the developer to work seamlessly with MySQL Connector/Net in the familiar Visual Studio environment, as described in the following sections of the manual.

MySQL Connector/Net supports Visual Studio versions 2005, 2008, and 2010. However, only MySQL Connector/Net version 6.3 and higher fully integrate with Visual Studio 2010, although applications using earlier versions of the connector can be built with the Visual Studio 2010 environment using .NET 2.x frameworks.

Visual Studio 2010 support was introduced with MySQL Connector/Net 6.3.2. From version 6.3.2 the connector ships with both .NET 2.x and .NET 4.x versions of the entity framework support files, `mysql.data.ef.dll` and `mysql.visualstudio.dll`. The .NET 4.x versions are required to enable new integration features supported in Visual Studio 2010, including:

- **New DDL T4 template for the Entity Framework (EF)** - This enables developers to design an EF model from scratch and use the native Visual Studio 2010 facility to generate MySQL DDL from that model. This is done by creating the model, and with the model open, choosing the `SSDLToMySQL` template in the properties window. The correct DDL is then generated. The developer can then save this code as a `.mysql` file in their project and execute it against the MySQL server.
- **New SQL Editor** - A new SQL editor lets you connect to a MySQL server to execute SQL. This is activated by creating a new file with a `.mysql` extension. A new template lets you create files with this file type using the Visual Studio 2010 main menu item **File**, **New**. Note that the MySQL SQL Editor is also available in Visual Studio 2005 and 2008.

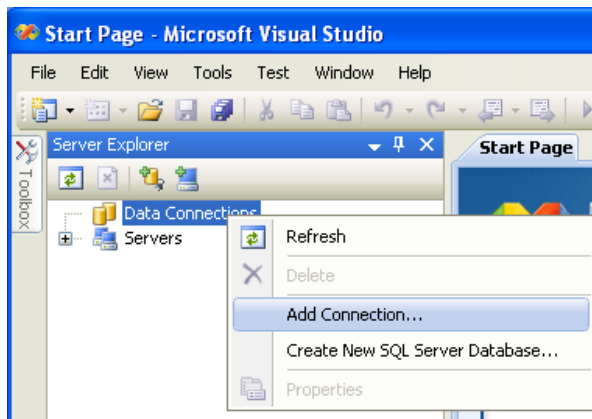

As of Connector/Net 5.1.2, the Visual Studio Plugin is part of the main Connector/Net package. However, even for versions of Connector/Net older than 5.1.2, the Visual Studio Plugin release notes can be found at [MySQL Connector/Net Release Notes](#).

22.2.3.1. Making a Connection

Once the connector is installed, you can use it to create, modify, and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

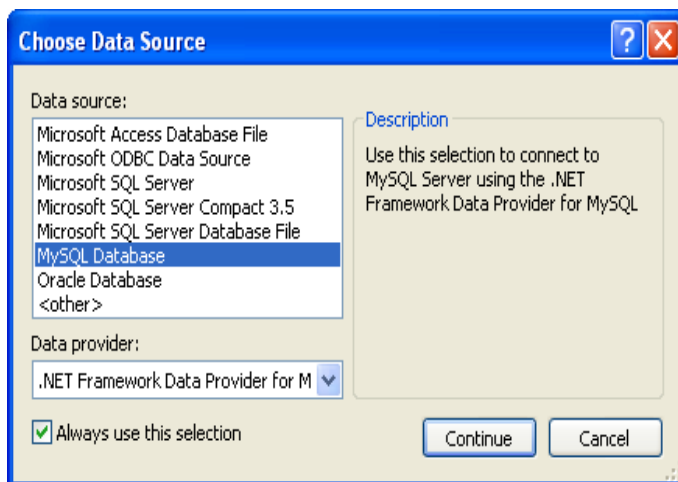

- Start Visual Studio, and open the Server Explorer window (View, Server Explorer option in the main Visual Studio menu, or **Control+W, L** keyboard shortcuts).
- Right-click the Data Connections node, and choose the **Add Connection...** menu item.
- Add Connection dialog opens. Press the **Change** button to choose MySQL Database as a data source.

Figure 22.1. Add Connection Context Menu

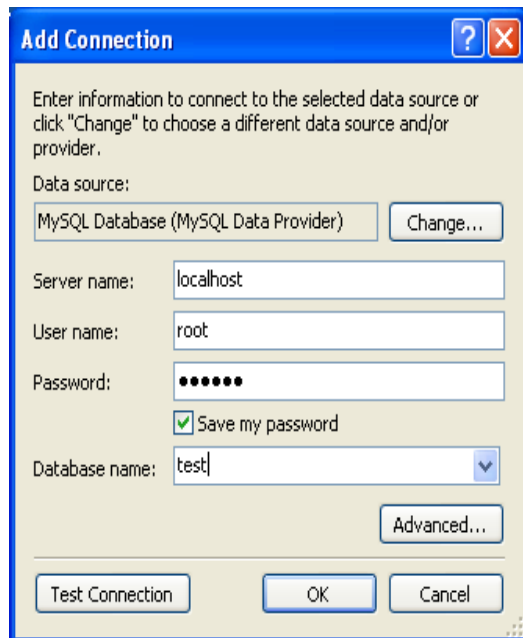

- **Change Data Source** dialog opens. Choose **MySQL Database** in the list of data sources (or the `<other>` option, if MySQL Database is absent), and then choose **.NET Framework Data Provider for MySQL** in the combo box of data providers.

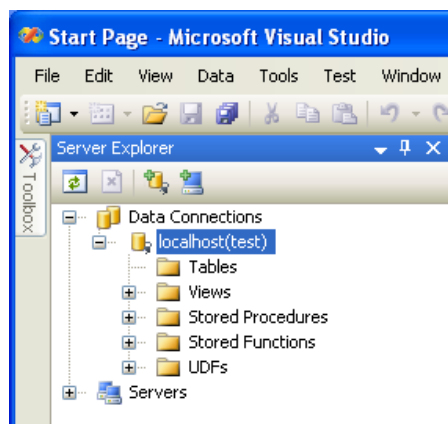

Figure 22.2. Choose Data Source

- Input the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default schema name. Note that you must specify the default schema name to open the connection.

Figure 22.3. Add Connection Dialog

- You can also set the port to connect with the MySQL server by pressing the **Advanced** button. To test connection with the MySQL server, set the server host name, the user name, and the password, and press the **Test Connection** button. If the test succeeds, the success confirmation dialog opens.
- After you set all settings and test the connection, press **OK**. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer GUI.

Figure 22.4. New Data Connection

After the connection is successfully established, all settings are saved for future use. When you start Visual Studio for the next time, open the connection node in Server Explorer to establish a connection to the MySQL server again.

To modify and delete a connection, use the Server Explorer context menu for the corresponding node. You can modify any of the settings by overwriting the existing values with new ones. Note that the connection may be modified or deleted only if no active editor for its objects is opened: otherwise, you may lose your data.

22.2.3.2. Using IntelliSense in the SQL Editor

IntelliSense support is available starting in Connector/Net 6.5. Once you have established a connection, for example, using the **Connect to MySQL** toolbar button, you can get autocompletion as you type, or by pressing **Control+J**. Depending on the context, the autocompletion dialog can show the list of available tables, table columns, or stored procedures (with the routine's signature as a tooltip). Typing some characters before pressing **Control+J** filters the choices to those items starting with that prefix.

22.2.3.3. Editing Tables

Connector/Net contains a table editor, which enables the visual creation and modification of tables.

The Table Designer can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right-click the **Tables** node (under the connection node) and choose the **Create Table** command from the context menu.

To modify an existing table, double-click the node of the table to modify, or right-click this node and choose the **Design** item from the context menu. Either of the commands opens the Table Designer.

The table editor is implemented in the manner of the well-known Query Browser Table Editor, but with minor differences.

Figure 22.5. Editing New Table

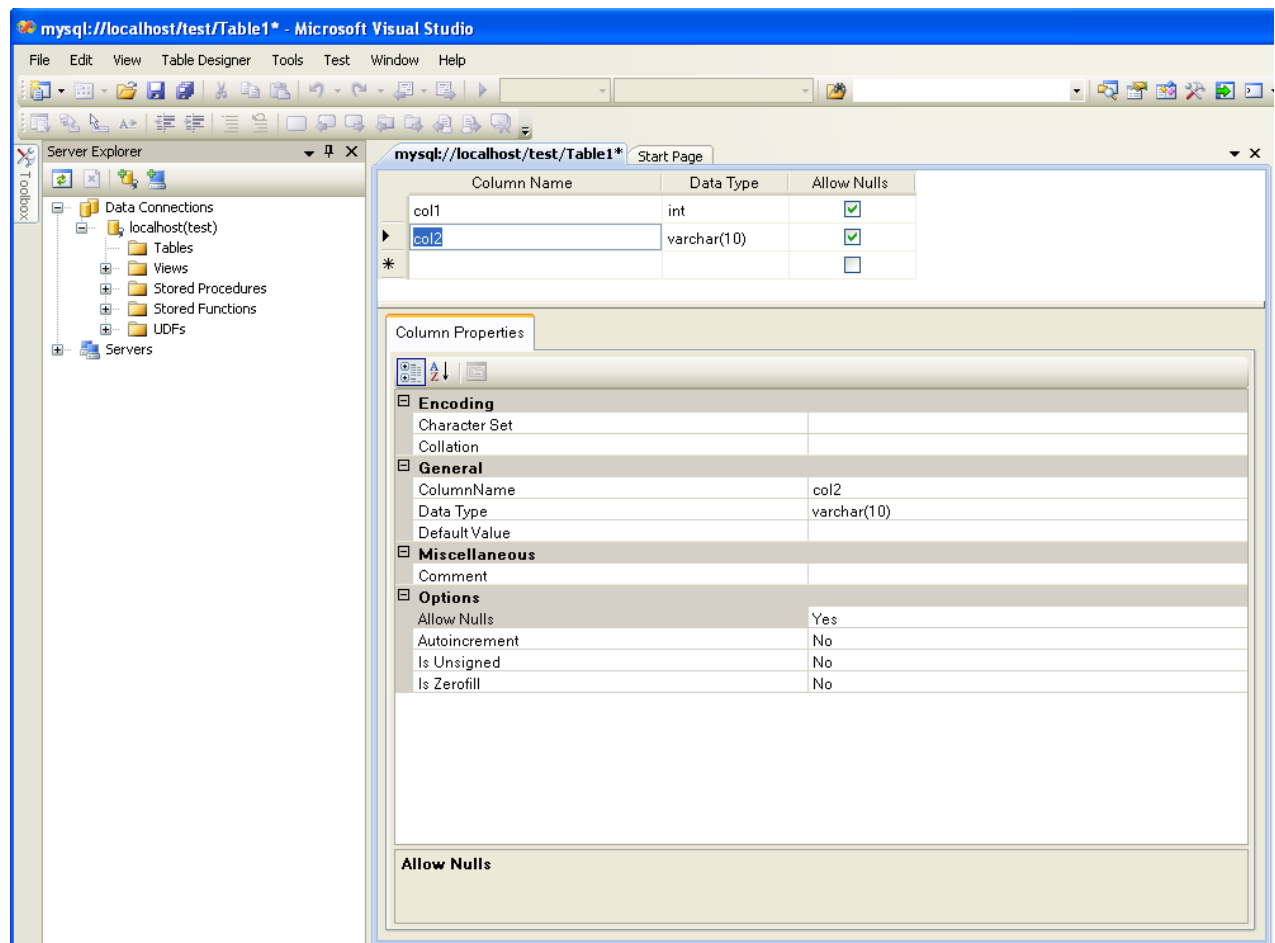

Table Designer consists of the following parts:

- Columns Editor - a data grid on top of the Table Designer. Use the Columns grid for column creation, modification, and deletion.
- Indexes tab - a tab on bottom of the Table Designer. Use the Indexes tab for indexes management.
- Foreign Keys tab - a tab on bottom of the Table Designer. Use the Foreign Keys tab for foreign keys management.
- Column Details tab - a tab on bottom of the Table Designer. Use the Column Details tab to set advanced column options.
- Properties window - a standard Visual Studio Properties window, where the properties of the edited table are displayed. Use the Properties window to set the table properties.

Each of these areas is discussed in more detail in subsequent sections.

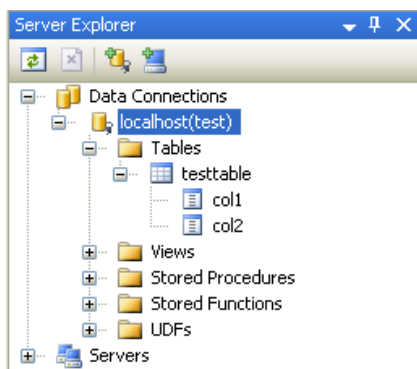

To save changes you have made in the Table Designer, use either **Save** or **Save All** button of the Visual Studio main toolbar, or press **Control+S**. If you have not already named the table, you will be prompted to do so.

Figure 22.6. Choose Table Name

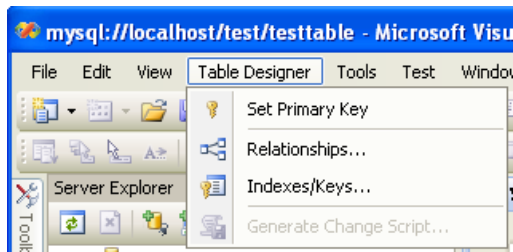

Once the table is created, you can view it in the Server Explorer.

Figure 22.7. Newly Created Table

The Table Designer main menu lets you set a [primary key](#) column, edit relationships such as [foreign keys](#), and create [indexes](#).

Figure 22.8. Table Designer Main Menu

22.2.3.3.1. Column Editor

You can use the Column Editor to set or change the name, data type, default value, and other properties of a table column. To set the focus to a needed cell of a grid, use the mouse click. Also you can move through the grid using **Tab** and **Shift+Tab** keys.

To set or change the name, data type, default value and comment of a column, activate the appropriate cell and type the desired value.

To set or unset flag-type column properties (**NOT NULL**, auto incremented, flags), check or uncheck the corresponding check boxes. Note that the set of column flags depends on its data type.

To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column to reorder by clicking the selector column on the left of the column grid. Then move the column by using **Control+Up** (to move the column up) or **Control+Down** (to move the column down) keys.

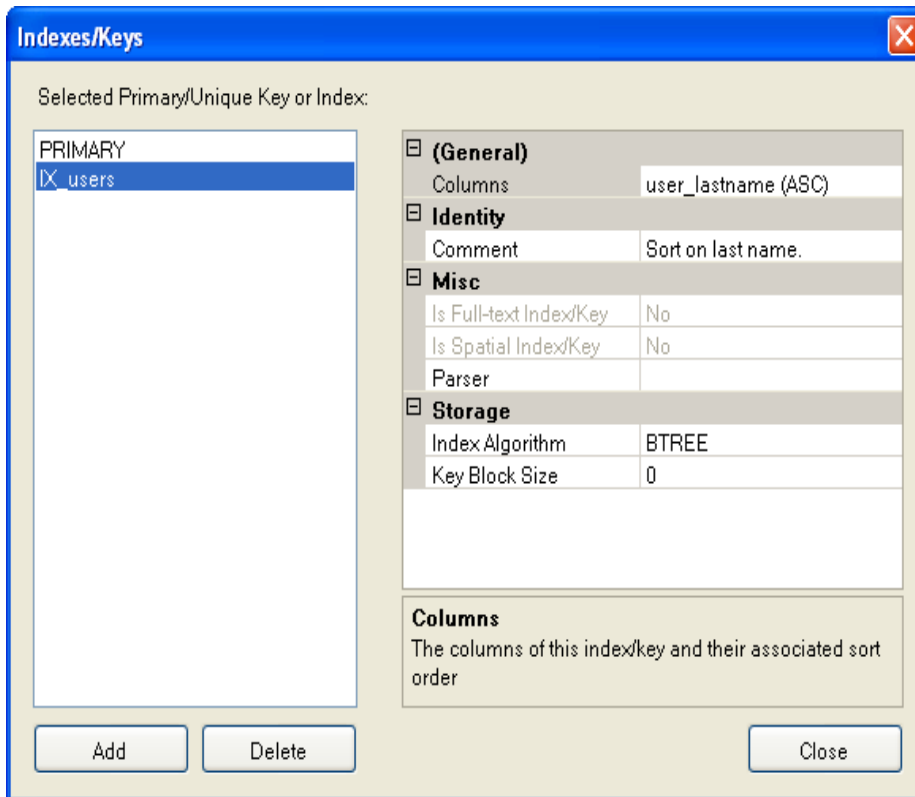

To delete a column, select it by clicking the selector column on the left of the column grid, then press the **Delete** button on a keyboard.

22.2.3.3.2. Editing Indexes

Indexes management is performed using the **Indexes/Keys** dialog.

To add an index, select **Table Designer, Indexes/Keys...** from the main menu, and click **Add** to add a new index. You can then set the index name, index kind, index type, and a set of index columns.

Figure 22.9. Indexes Dialog

To remove an index, select it in the list box on the left, and click the **Delete** button.

To change index settings, select the needed index in the list box on the left. The detailed information about the index is displayed in the panel on the right hand side. Change the desired values.

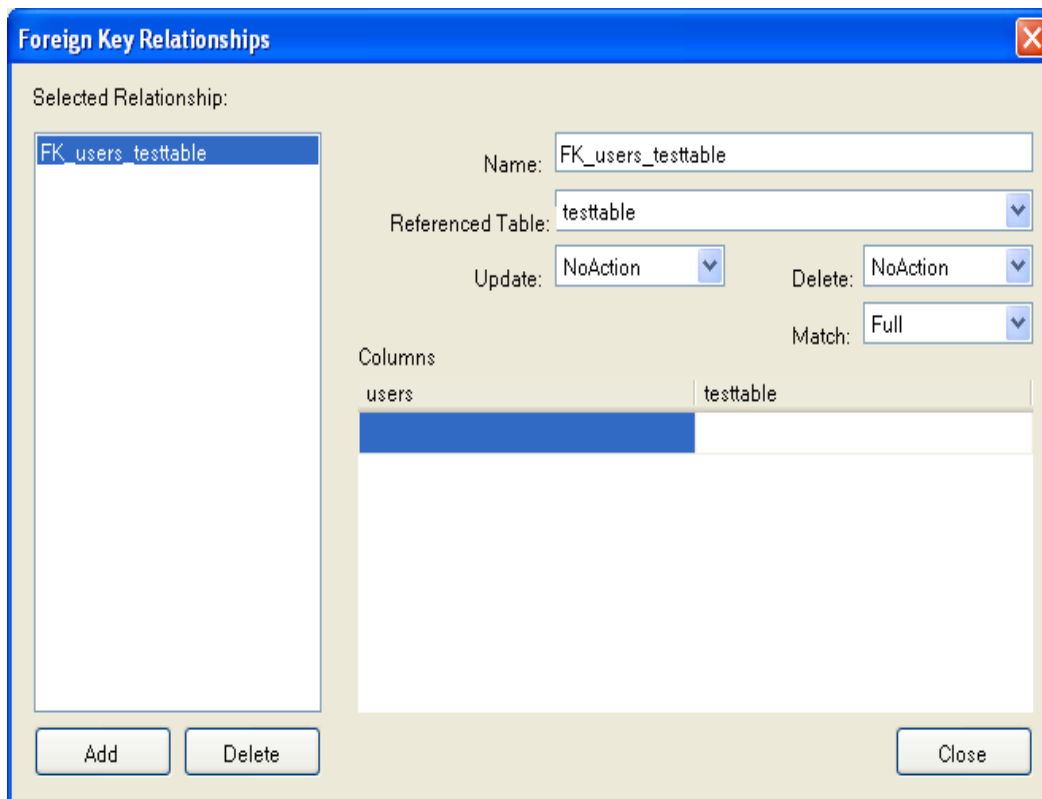

22.2.3.3.3. Editing Foreign Keys

You manage [foreign keys](#) for [InnoDB](#) tables using the **Foreign Key Relationships** dialog.

To add a foreign key, select **Table Designer, Relationships...** from the main menu. This displays the **Foreign Key Relationship** dialog. Click **Add**. You can then set the foreign key name, referenced table name, foreign key columns, and actions upon update and delete.

To remove a foreign key, select it in the list box on the left, and click the **Delete** button.

To change foreign key settings, select the required foreign key in the list box on the left. The detailed information about the foreign key is displayed in the right hand panel. Change the desired values.

Figure 22.10. Foreign Key Relationships Dialog

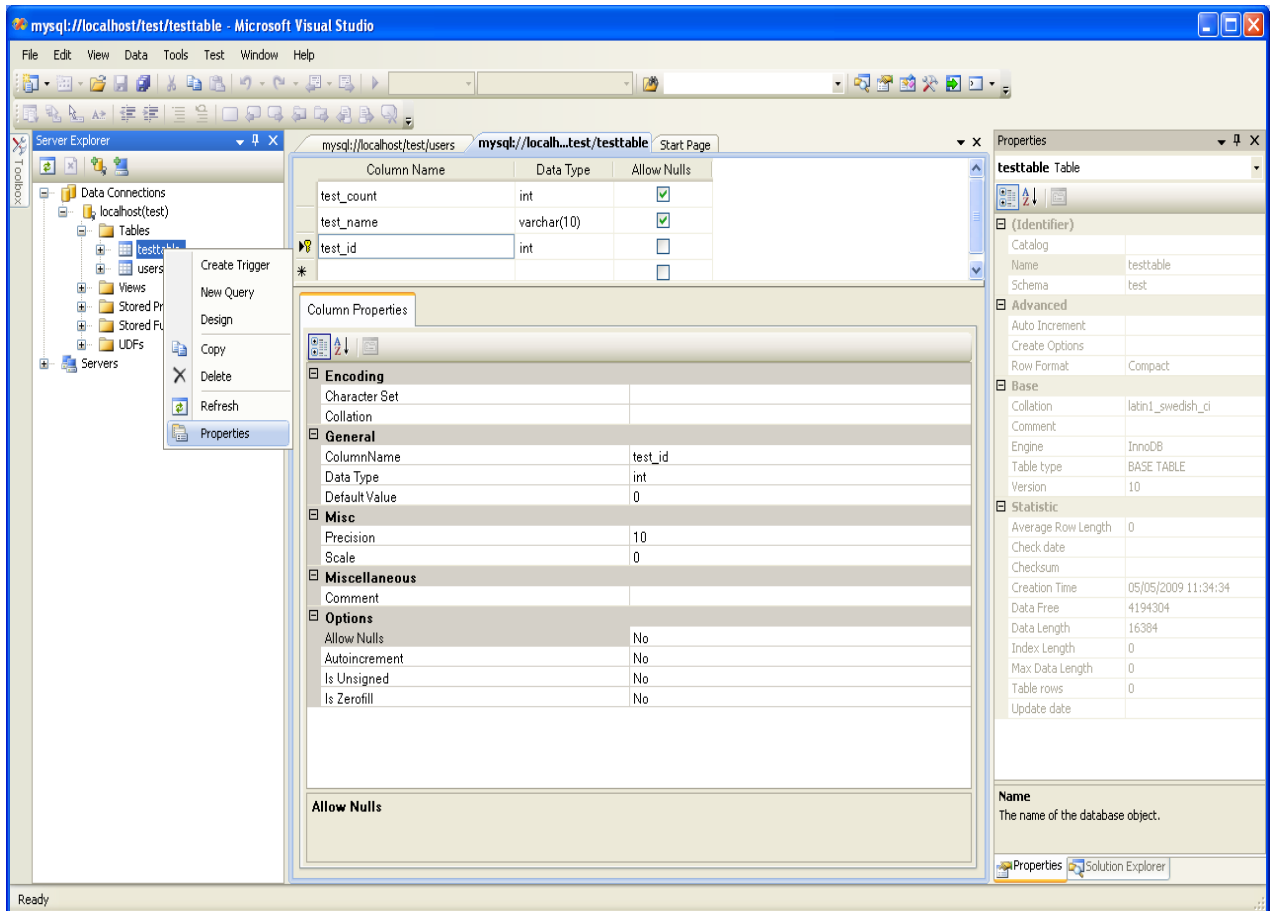

22.2.3.3.4. Column Properties

The **Column Properties** tab can be used to set column options. In addition to the general column properties presented in the Column Editor, in the **Column Properties** tab you can set additional properties such as Character Set, Collation and Precision.

22.2.3.3.5. Table Properties

To bring up Table Properties select the table and right-click to activate the context menu. Select Properties. The **Table Properties** dockable window will be displayed.

Figure 22.11. Table Properties Menu Item

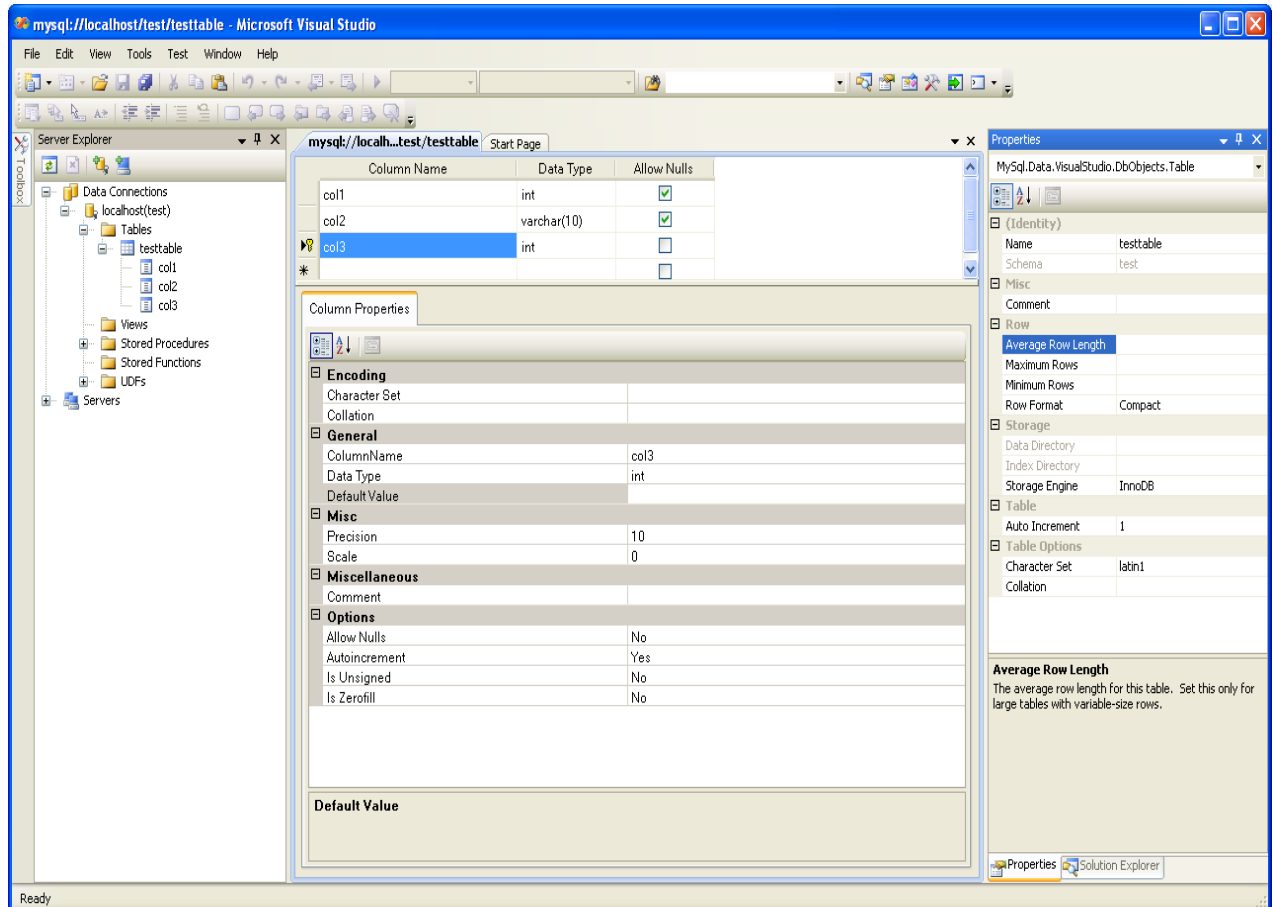

The following table properties can be set:

- Auto Increment.
- Average Row Length.
- Character Set.
- Collation.
- Comment.
- Data Directory.
- Index Directory.
- Maximum Rows.
- Minimum Rows.
- Name.
- Row Format.
- Schema.

- **Storage Engine.** Note that in MySQL 5.5 and higher, the default storage engine for new tables is [InnoDB](#). See [Section 14.3.1, “InnoDB as the Default MySQL Storage Engine”](#) for more information about the choice of storage engine, and considerations if you convert existing tables to [InnoDB](#).

The property [Schema](#) is read-only.

Figure 22.12. Table Properties

22.2.3.4. Editing Views

To create a new view, right-click the Views node under the connection node in Server Explorer. From the node's context menu, choose the [Create View](#) command. This command opens the SQL Editor.

Figure 22.13. Editing View SQL

You can then enter the SQL for your view.

Figure 22.14. View SQL Added

To modify an existing view, double-click a node of the view to modify, or right-click this node and choose the Alter View command from a context menu. Either of the commands opens the SQL Editor.

All other view properties can be set in the Properties window. These properties are:

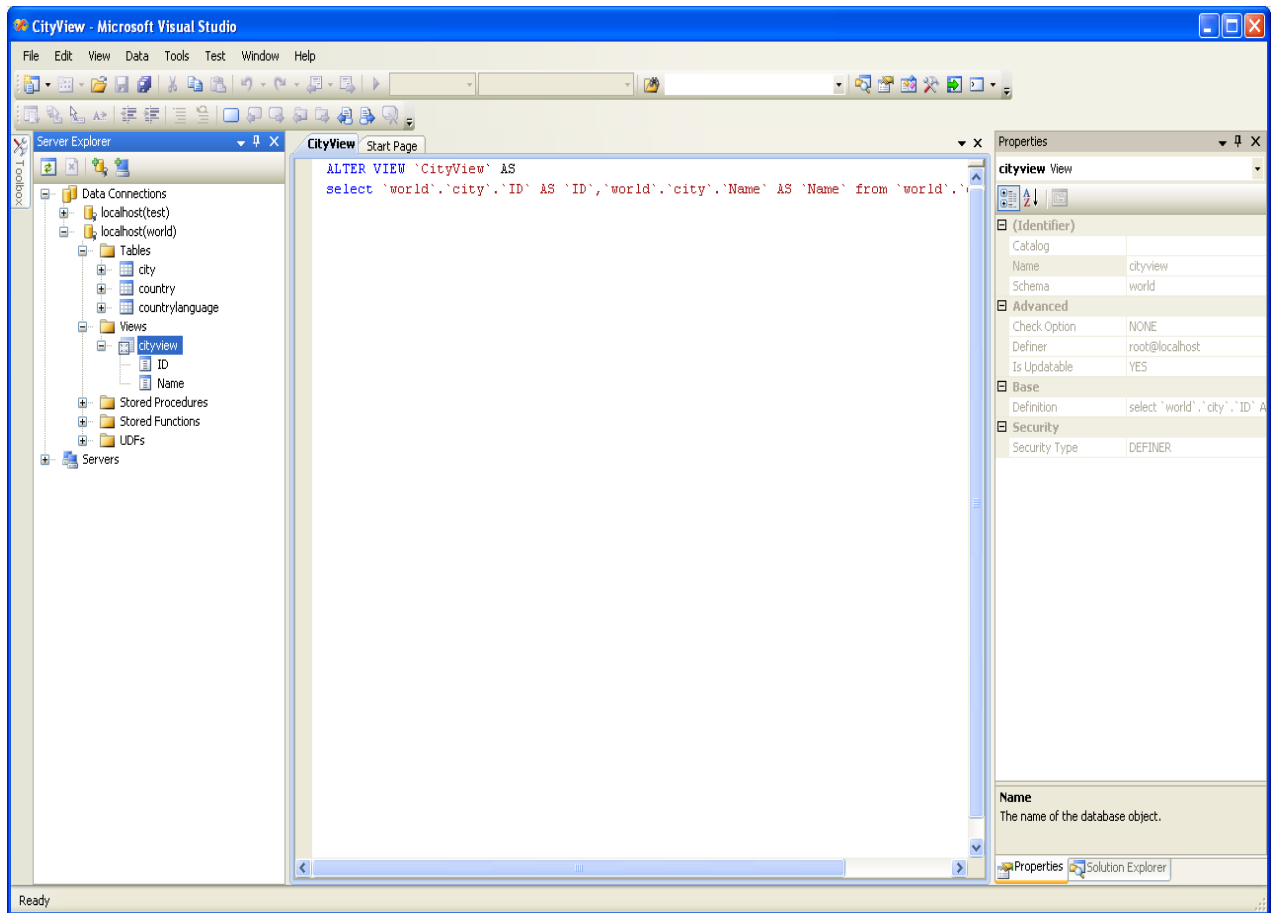

- Catalog
- Check Option
- Definer
- Definition
- Definer
- Is Updatable
- Name
- Schema
- Security Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value with an embedded combobox.

The properties *Is Updatable* and *Schema* are readonly.

To save changes you have made, use either Save or Save All buttons of the Visual Studio main toolbar, or press **Control+S**.

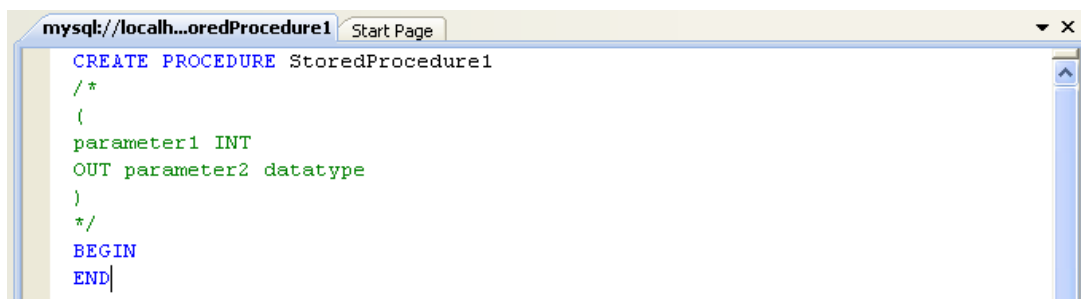

Figure 22.15. View SQL Saved

22.2.3.5. Editing Stored Procedures and Functions

To create a new stored procedure, right-click the **Stored Procedures** node under the connection node in Server Explorer. From the node's context menu, choose the **Create Routine** command. This command opens the SQL Editor.

Figure 22.16. Edit Stored Procedure SQL

To create a new stored function, right-click the **Functions** node under the connection node in Server Explorer. From the node's context menu, choose the **Create Routine** command.

To modify an existing stored routine (procedure or function), double-click the node of the routine to modify, or right-click this node and choose the **Alter Routine** command from the context menu. Either of the commands opens the SQL Editor.

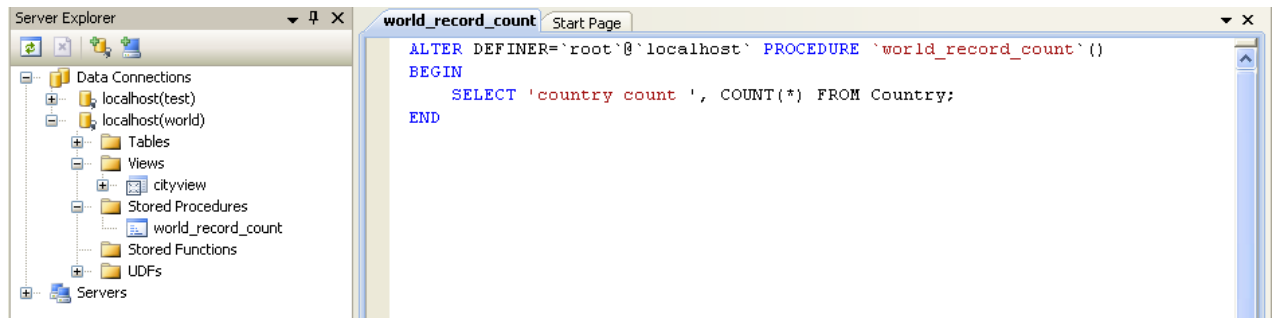

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL. All other routine properties can be set in the Properties window. These properties are:

- Body
- Catalog
- Comment
- Creation Time
- Data Access
- Definer
- Definition
- External Name
- External Language
- Is Deterministic
- Last Modified
- Name
- Parameter Style
- Returns
- Schema
- Security Type
- Specific Name
- SQL Mode
- SQL Path
- Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value using the embedded combo box.

You can also set all the options directly in the SQL Editor, using the standard `CREATE PROCEDURE` or `CREATE FUNCTION` statement. However, it is recommended to use the Properties window instead.

To save changes you have made, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**.

Figure 22.17. Stored Procedure SQL Saved

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See [Section 22.2.3.8, “Debugging Stored Procedures and Functions”](#) for details.

22.2.3.6. Editing Triggers

To create a new trigger, right-click the node of the table in which to add the trigger. From the node's context menu, choose the **Create Trigger** command. This command opens the SQL Editor.

To modify an existing trigger, double-click the node of the trigger to modify, or right-click this node and choose the **Alter Trigger** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

Note

Enter only the trigger statement, that is, the part of the `CREATE TRIGGER` query that is placed after the `FOR EACH ROW` clause.

All other trigger properties are set in the Properties window. These properties are:

- Definer
- Event Manipulation
- Name
- Timing

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case, set the desired value using the embedded combo box.

The properties `Event Table`, `Schema`, and `Server` in the Properties window are read-only.

To save changes you have made, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See [Section 22.2.3.8, “Debugging Stored Procedures and Functions”](#) for details.

22.2.3.7. Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right-click the **UDFs** node under the connection node in Server Explorer. From the node's context menu, choose the **Create UDF** command. This command opens the UDF Editor.

To modify an existing UDF, double-click the node of the UDF to modify, or right-click this node and choose the **Alter UDF** command from the context menu. Either of these commands opens the UDF Editor.

The UDF editor enables you to set the following properties:

- Name
- So-name (DLL name)
- Return type
- Is Aggregate

There are text fields for both names, a combo box for the return type, and a check box to indicate if the UDF is aggregate. All these options are also accessible using the Properties window.

The property `Server` in the Properties window is read-only.

To save changes you have made, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

To observe the runtime behavior of a stored routine and debug any problems, use the Stored Procedure Debugger (available in Connector/Net 6.6 and higher). See [Section 22.2.3.8, "Debugging Stored Procedures and Functions"](#) for details.

22.2.3.8. Debugging Stored Procedures and Functions

The stored procedure debugger, new in Connector/Net 6.6, provides facilities for setting breakpoints, stepping into individual statements (Step Into, Step Out, Step Over), evaluating and changing local variable values, evaluating breakpoints, and other typical debugging tasks.

Installing the Debugger

To enable the stored procedure debugger, install Connector/Net 6.6 or higher and choose the **Complete** option.

Privileges

The debugger recreates at the start of each debug session a `serversidedebugger` database in your server. This database helps to track the instrumented code and implement observability logic in the debugged routine. Your current connection needs to have privileges to create that database, and its associated stored routines, functions, and tables.

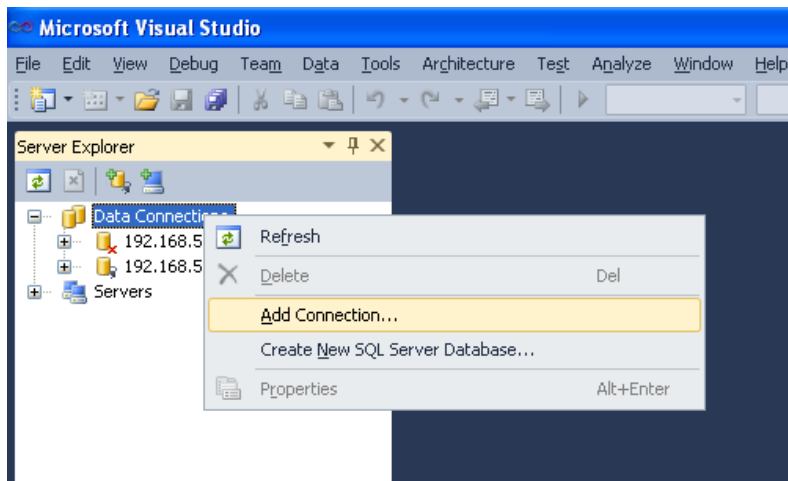

The debugger makes changes behind the scenes to temporarily add instrumentation code to the stored routines that you debug. You must have the `ALTER ROUTINE` privilege for each stored procedure, function, or trigger that you debug. (Including procedures and functions that are called, and triggers that are fired, by a procedure that you are debugging.)

Starting the Debugger

To start the debugger, follow these steps:

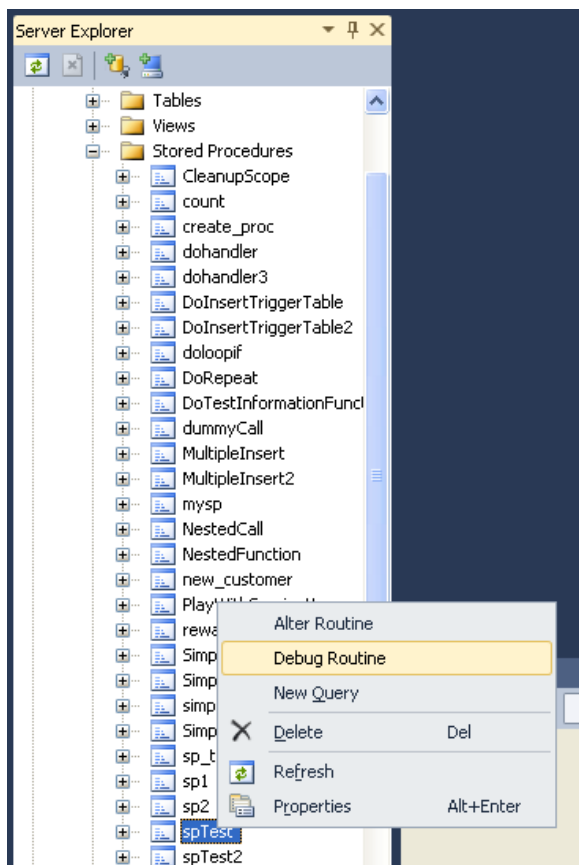

- Choose a connection in the Visual Studio Server Explorer.

Figure 22.18. Connection Dialog

- Expand the **Stored Procedures** folder. Only stored procedures can be debugged directly. To debug a user-defined function, create a stored procedure that calls the function.
- Click on a stored procedure node, then right-click and from the context menu choose **Debug Routine**.

Figure 22.19. Choose a Stored Routine to Debug

At this point, Visual Studio switches to debug mode, opening the source code of the routine being debugged in step mode, positioned on the first statement.

If the initial routine you debug has one or more arguments, a popup will show up with a grid (a row per each argument and three columns: one for the argument, one for the argument value (this is editable) and one for nullifying that argument value (a checkbox)). After setting up all the argument values, you can press **OK** to start the debug session, or **Cancel** to cancel the debug session.

Figure 22.20. Setting Arguments (1 of 2)

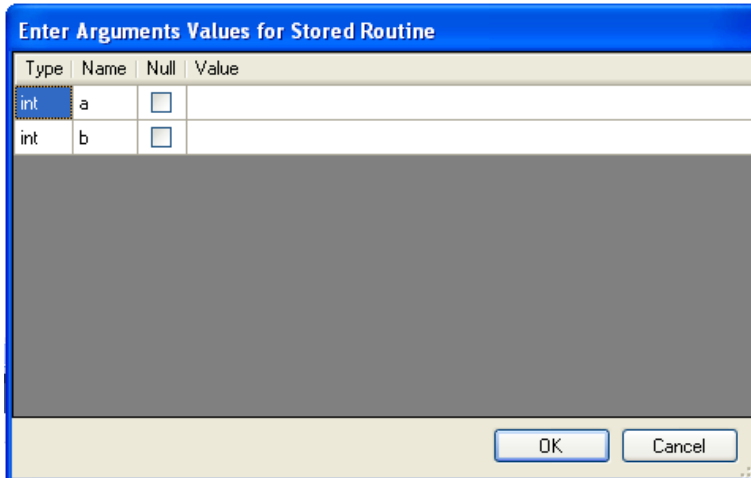

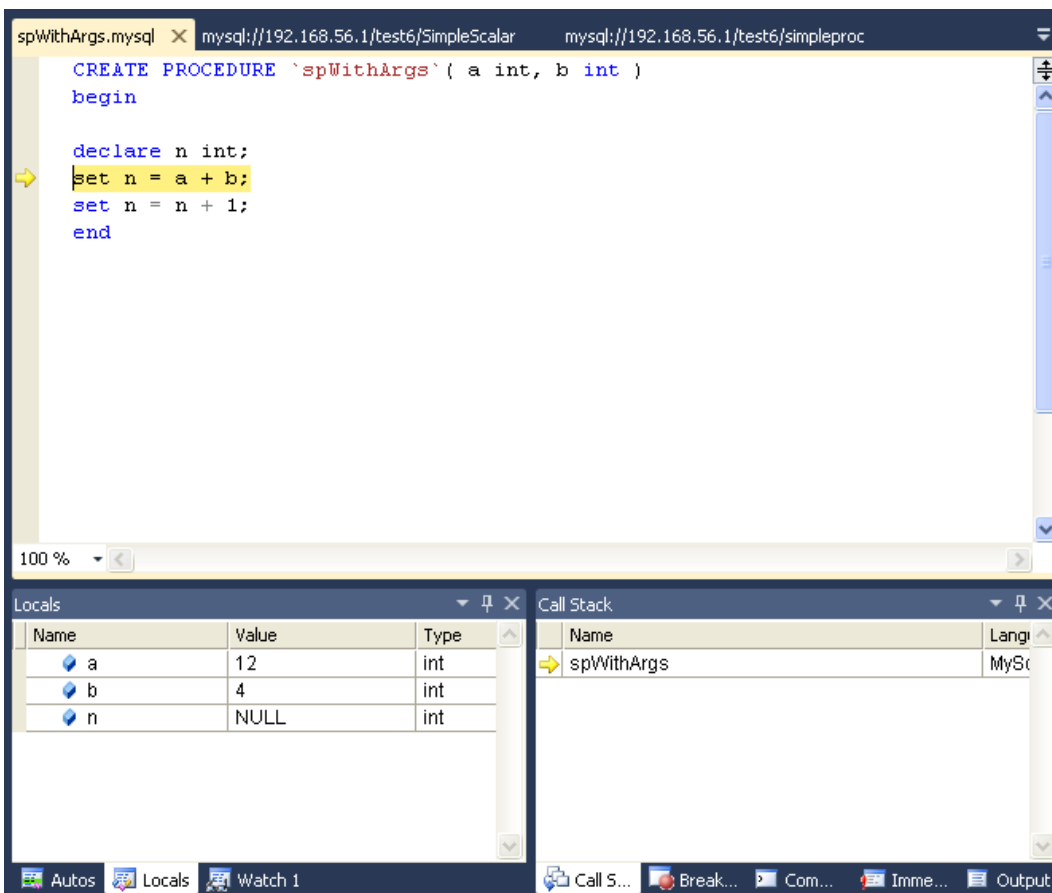

Figure 22.21. Setting Arguments (2 of 2)

How the Debugger Works

To have visibility into the internal workings of a stored routine, the debugger prepares a special version of the procedure, function, or trigger being debugged, instrumented with extra code to keep track of the current line being stepped into and the values of all the local variables. Any other stored procedures, functions, or triggers called from the routine being debugged are instrumented the same way. The debug versions of the routines are prepared for you automatically, and when the debug session ends (by either pressing **F5** or **Shift+F5**), the original versions of the routines are automatically restored.

A copy of the original version of each instrumented routine (the version without instrumentation) is stored in the `AppData\Roaming\MySQLDebuggerCache` folder for the current Windows user (the path returned by calling `System.Environment.GetFolderPath(Environment.SpecialFolder.ApplicationData)` in .NET, plus appending `MySQLDebuggerCache`. There is one file for each instrumented routine, named `routine_name.mysql`. For example, in Windows 7, for a user named `fergs`, the path is `C:\Users\fergs\AppData\Roaming\MySQLDebuggerCache`.

Two threads are used, one for the debugger and one for the routine being debugged. The threads run in strict alternation, switching between the debugger and the routine as each statement is executed in the stored routine.

Basic Debugging Operations

The debugger has the same look and feel as the standard Visual Studio debuggers for C#, VB.NET or C++. In particular, the following are true:

Locals and Watches

- To show the Locals tab, choose the menu item **Debug -> Windows -> Locals**.

The **Locals** tab lists all the variables available in the current scope: variables defined with `DECLARE` at any point in the routine, argument parameters, and session variables that are referenced.

- If the last step operation changes the value of a local, its value will be highlighted in red (until another statement is executed or stepped).
- You can change the value of any local.
- To show the **Watch** tab, choose the menu item **Debug -> Windows -> Watch**.

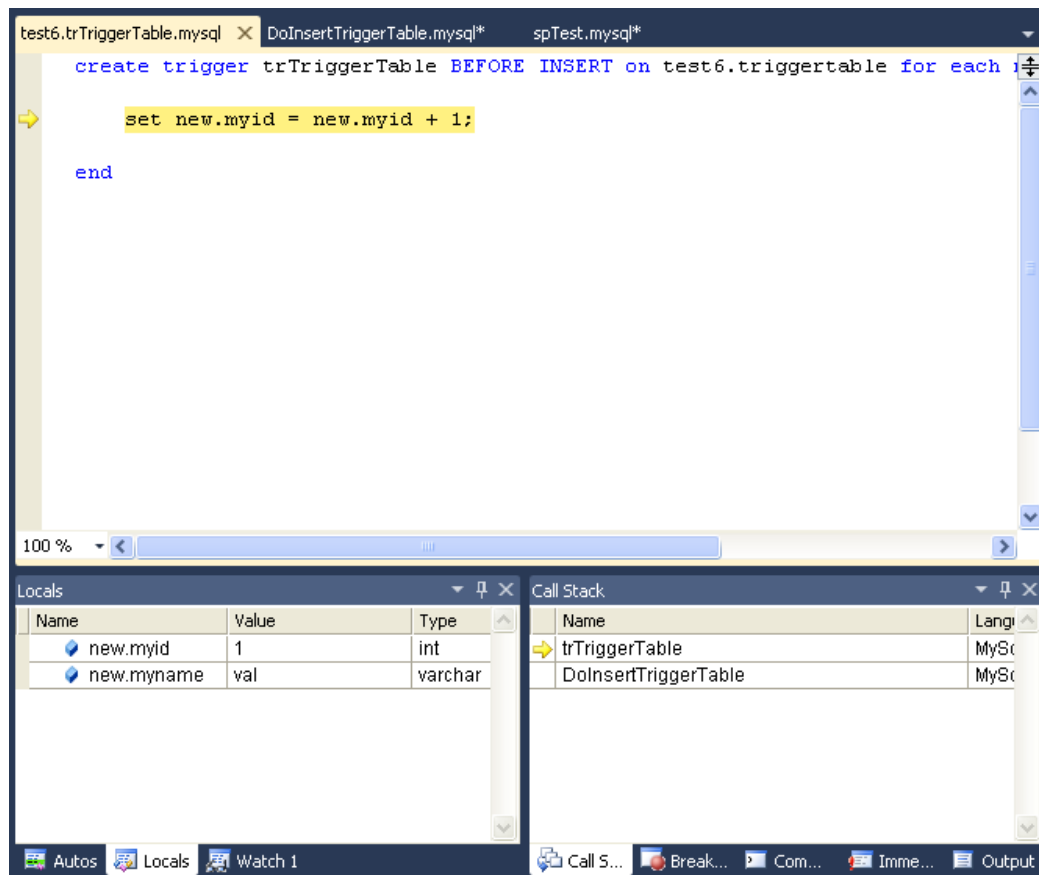

To define a watch, type any valid MySQL expression, optionally including function calls. If the watch evaluation makes sense in the current context (current stack frame), it will show its value, otherwise it will show an error message in the same row the watch was defined.

- When debugging a trigger, in addition to any locals declared or session variables referenced, the new and old object (when applicable) will be listed. For example in a trigger for `INSERT`, for a table defined like:

```
create table t1( id int, myname varchar( 50 ));
```

the locals will list the extra variables `new.id` and `new.myname`. For an `UPDATE` trigger, you will also get the extra variables `old.id` and `old.myname`. These variables from the new and old objects can be manipulated the same way as any ordinary local variable.

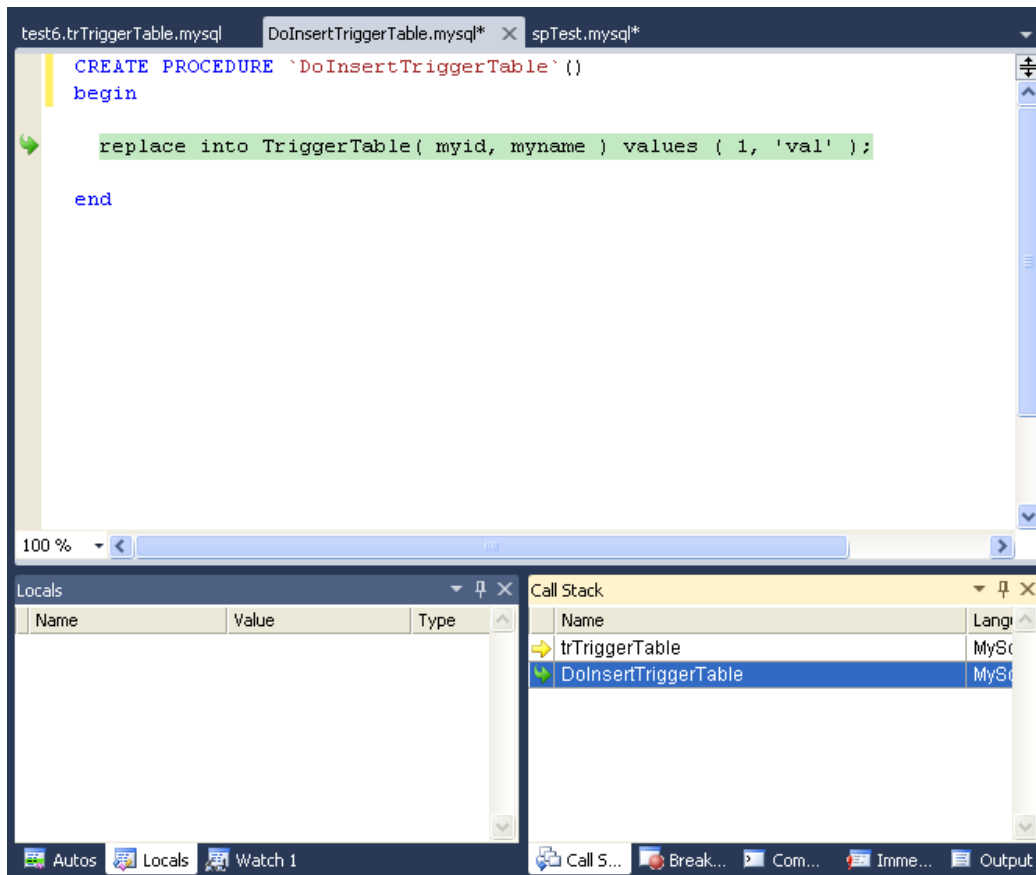

Figure 22.22. Debugging a Trigger

Call Stack

- To show the **Call Stack** tab, choose the menu item **Debug -> Windows -> Call Stack**.
- The stack trace (in the **Call Stack** tab) will list all the stack traces, one for each routine invocation. The one with a yellow mark is the current stepping point. Clicking in another will activate in the editor the tab for that routine source, highlighting in green the last statement stepped.

Figure 22.23. Call Stack

Stepping

- Stepping of a new routine starts in the first executable instruction (excluding declares, handlers, cursor declarations, and so on).

Figure 22.24. Debug Stepping

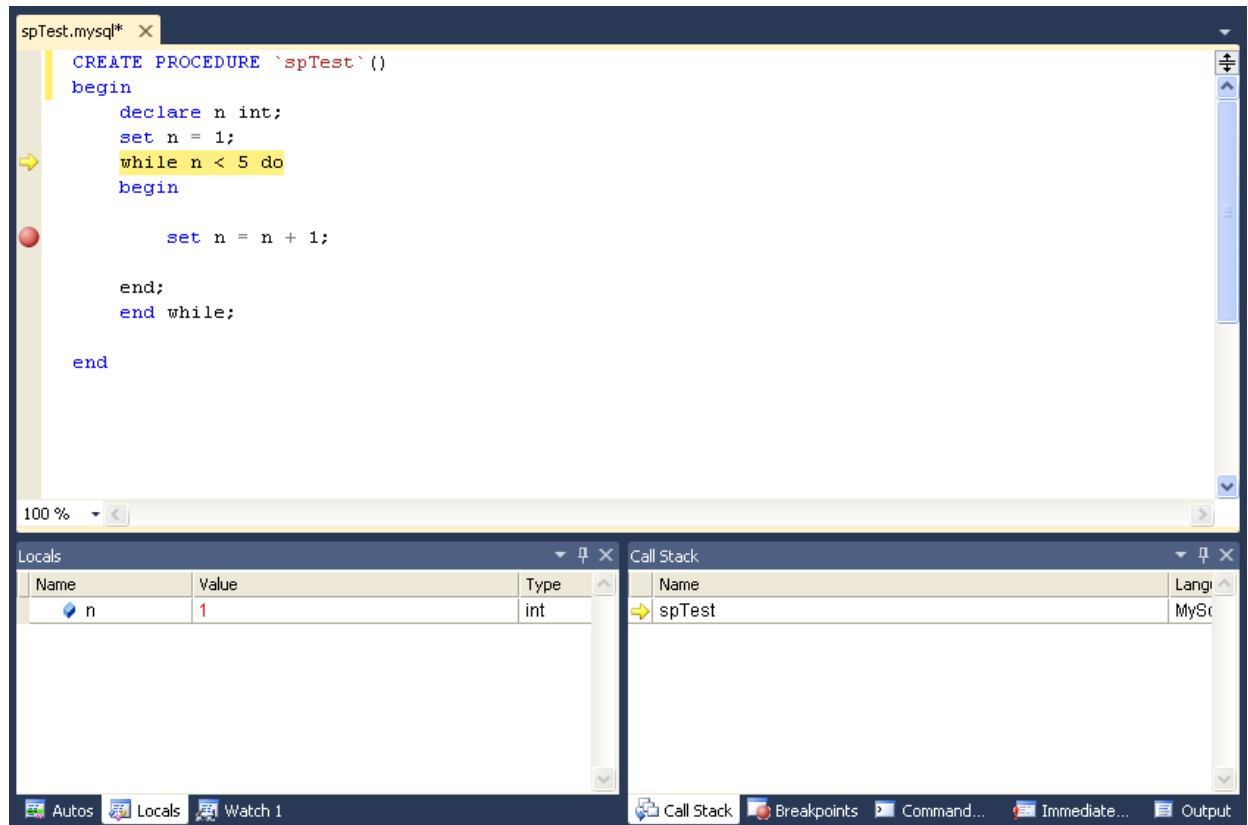

Figure 22.25. Function Stepping (1 of 2)

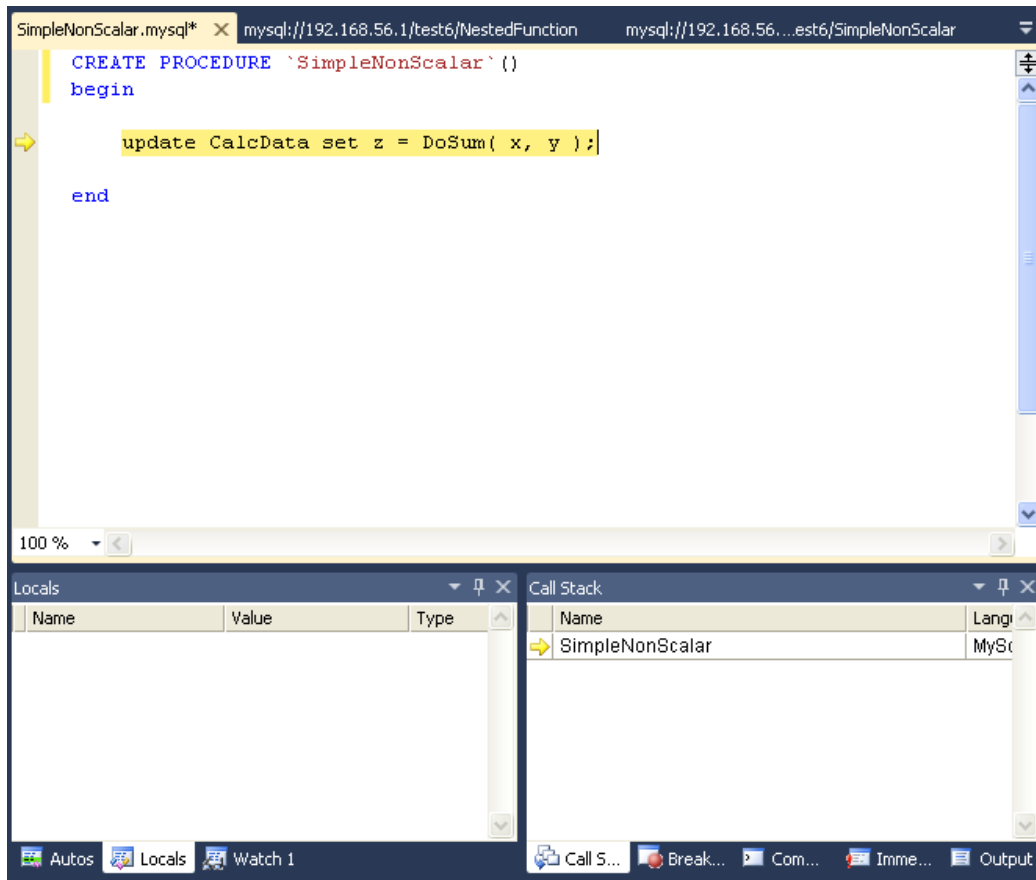

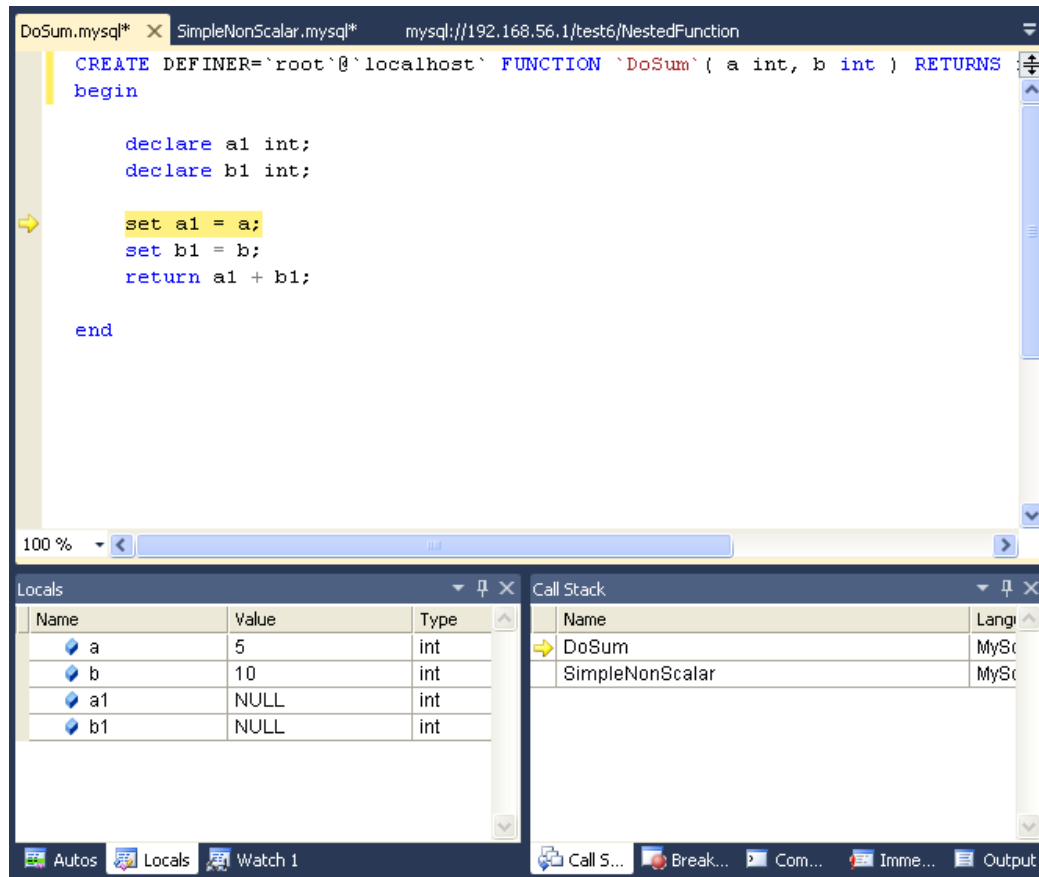

Figure 22.26. Function Stepping (2 of 2)

- To step into the code of a condition handler, the condition must be triggered in the rest of the MySQL routine.
- The next statement to be executed is highlighted in yellow.
- To continue stepping, you can choose between **Step Into** (by pressing **F11**), **Step Out** (by pressing **F10**) or **Step Over** (by pressing **Shift+F11**).
- You can step out of any of functions, triggers or stored procedures. If you step from the main routine, it will run that routine to completion and finish the debug session.
- You can step over stored procedure calls, stored functions, and triggers. (To step over a trigger, step over the statement that would cause the trigger to fire.)
- When stepping into a single statement, the debugger will step into each individual function invoked by that statement and each trigger fired by that statement. The order in which they are debugged is the same order in which the MySQL server executes them.
- You can step into triggers triggered from **INSERT**, **DELETE**, **UPDATE**, and **REPLACE** statements.
- Also, the number of times you enter into a stored function or trigger depends on how many rows are evaluated by the function or affected by the trigger. For example, if you press **F11 (Step Into)** into an **UPDATE** statement that modifies three rows (calling a function for a column in the **SET** clause, thus invoking the function for each of the three rows), you will step into into that function three times in succession, once for each of the rows. You can accelerate this debug session by disabling any

breakpoints defined in the given stored function and pressing **Shift+F11** to step out. In this example, the order in which the different instances of the stored function are debugged is server-specific: the same order used by the current MySQL server instance to evaluate the three function invocations.

Breakpoints

- To show the **Breakpoints** tab, choose the menu item **Debug -> Windows -> Breakpoints**.
- The **Breakpoints** tab will show all the breakpoints defined. From here, you can enable and disable breakpoints one by one or all at once (using the toolbar on top of the **Breakpoints** tab).
- You can define new breakpoints only in the middle of a debug session. Click in the left gray border of any MySQL editor, or click anywhere in a MySQL editor and press **F9**. In the familiar Visual Studio way, you press **F9** once to create a breakpoint in that line, and press it again to remove that breakpoint.
- Once a breakpoint is defined, it will appear enabled (as filled red circle left to the current row if that line is a valid statement to put a breakpoint) or disabled (as a non-filled red circle left to the current row if that row is not valid to put a breakpoint).
- To define conditional breakpoints, after creating the breakpoint, right click in the red dot and choose **Condition...**. There you can put any valid MySQL expression and state if the condition is **Is True** or **Has changed**. The former will trigger the breakpoint every time the condition is true, the latter every time the condition value has changed. (If you define a conditional breakpoint, it is not enough to step into the line with the breakpoint defined to trigger such a breakpoint.)

Figure 22.27. Conditional Breakpoints

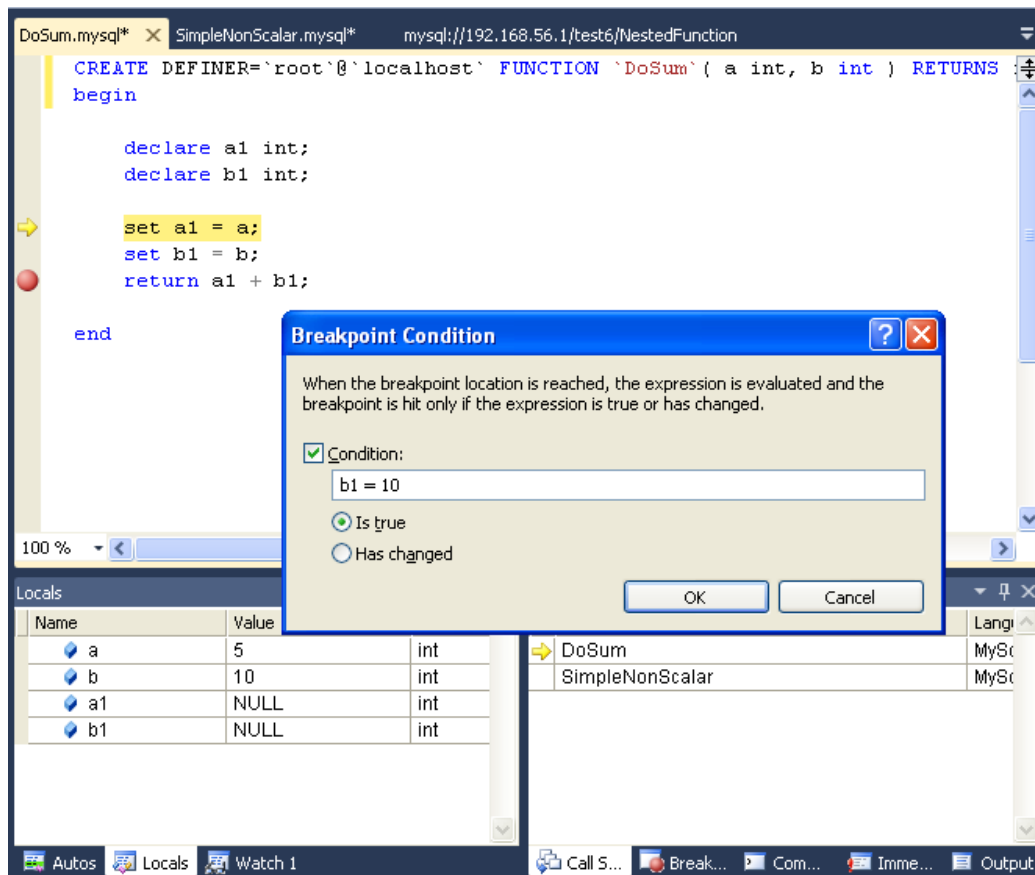

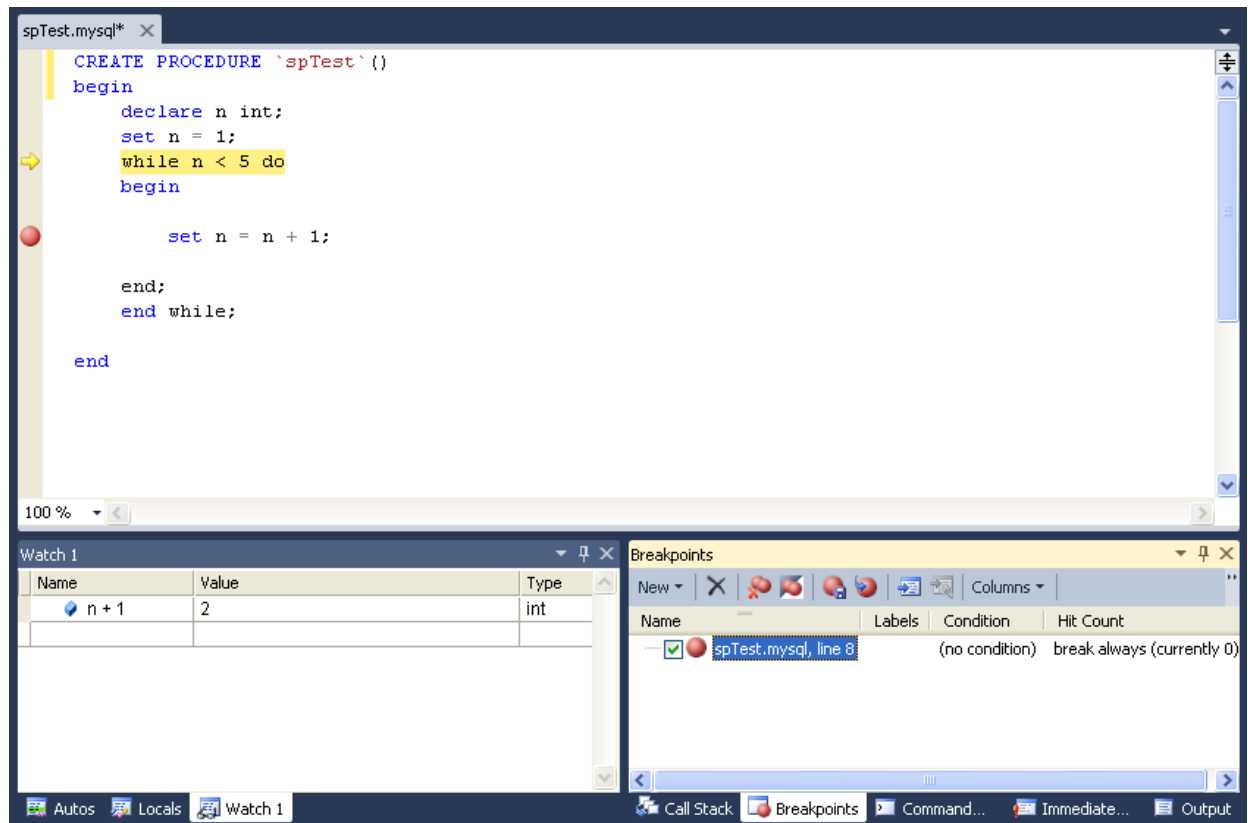

Figure 22.28. Expressions and Breakpoints

- To define pass count breakpoints, after creating the breakpoint, right click in the red dot and choose **Hit Count...**. In the popup dialog, define the specific condition to set. For example, **break when the hit count is equal to** and a value 3 will trigger the breakpoint the third time it is hit.

Other Features

- To abort the debug session (and the execution of the current call stack of routines), press Shift+F5.
- To run the routine to completion (or until next breakpoint hit), press F5.
- For all functionality you can use (in addition to the shortcuts documented), see the options in the **Debug** menu of Visual Studio.

Limitations

- Code being debugged must not use `get_lock` or `release_lock` MySQL functions, since they are used internally by the debugger infrastructure to synchronize the debugger and the debugged routine.
- Code being debugged must avoid using any transaction code (`START TRANSACTION`, `COMMIT`, `ROLLBACK`) due to the possibility of wiping out the contents of the debugger tables. (This limitation may be removed in the future).
- You cannot debug the routines in the `serversidedebugger` database.
- The MySQL server running the routine being debugged can be any version between 5.0 and 5.6, running on Windows, Linux, or any other supported platform.

- We recommend always running debug sessions on test and development servers, rather than against a MySQL production server, because debugging can cause temporary performance issues or even deadlocks. The instrumented versions of the routines being debugged use locks, that the rest of the production code may not be aware of.

Keyboard Shortcuts

The following list summarizes the keyboard shortcuts for debugging:

- **F9** Toggles breakpoints
- **F11**: Step into once
- **F10**: Step over once
- **Shift+F11**: Step out once
- **F5**: Run
- **Shift+F5**: Abort current debug session

22.2.3.9. Cloning Database Objects

Tables, views, stored procedures, and functions can be cloned using the appropriate Clone command from the context menu: [Clone Table](#), [Clone View](#), [Clone Routine](#). The clone commands open the corresponding editor for a new object: the **Table Editor** for cloning a table, and the **SQL Editor** for cloning a view or a routine.

The editor is filled with values of the original object. You can modify these values in the usual manner.

To save the cloned object, use either **Save** or **Save All** buttons of the Visual Studio main toolbar, or press **Control+S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

22.2.3.10. Dropping Database Objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate Drop command selected from its context menu: [Drop Table](#), [Drop View](#), [Drop Routine](#), [Drop Trigger](#), [Drop UDF](#).

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

You can only drop a single object at a time.

22.2.3.11. Using the ADO.NET Entity Framework

Connector/Net 6.0 introduced support for the ADO.NET Entity Framework. ADO.NET Entity Framework was included with .NET Framework 3.5 Service Pack 1, and Visual Studio 2008 Service Pack 1. ADO.NET Entity Framework was released on 11th August 2008.

ADO.NET Entity Framework provides an Object Relational Mapping (ORM) service, mapping the relational database schema to objects. The ADO.NET Entity Framework defines several layers, these can be summarized as:

- **Logical** - this layer defines the relational data and is defined by the Store Schema Definition Language (SSDL).

- **Conceptual** - this layer defines the .NET classes and is defined by the Conceptual Schema Definition Language (CSDL)
- **Mapping** - this layer defines the mapping from .NET classes to relational tables and associations, and is defined by Mapping Specification Language (MSL).

Connector/Net integrates with Visual Studio 2008 to provide a range of helpful tools to assist the developer.

A full treatment of ADO.NET Entity Framework is beyond the scope of this manual. If you are unfamiliar with ADO.NET, review the [Microsoft ADO.NET Entity Framework documentation](#).

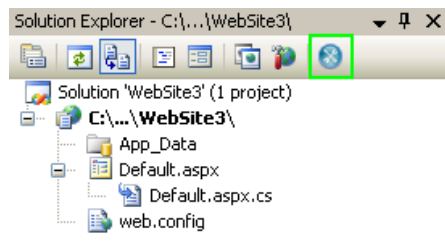

Tutorials on getting started with ADO.NET Entity Framework are available. See [Section 22.2.4.5, "Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source"](#) and [Section 22.2.4.6, "Tutorial: Databinding in ASP.NET using LINQ on Entities"](#).

22.2.3.12. MySQL Website Configuration Tool

MySQL Connector/Net 6.1 introduced the MySQL Website Configuration Tool. This is a facility available in Visual Studio that enables you to configure the Membership, Role, Session State and Profile Provider, without editing configuration files. You set your configuration options within the tool, and the tool modifies your `web.config` file accordingly.

The MySQL Website Configuration Tool appears as a small icon on the Solution Explorer toolbar in Visual Studio, as show by the following screenshot:

Figure 22.29. MySQL Website Configuration Tool

Clicking the Website Configuration Tool icon launches the wizard and displays the first screen:

Figure 22.30. MySQL Website Configuration Tool - Membership

The screenshot shows a dialog box titled "MySQL Website Configuration" with a "Membership" tab. The dialog has a blue header bar with a close button (X) in the top right corner. Below the header, the text "Membership" is displayed in bold, followed by the instruction "Set options for use with the membership provider". A gear icon is visible in the top right corner of the main content area. The main content area contains the following elements:

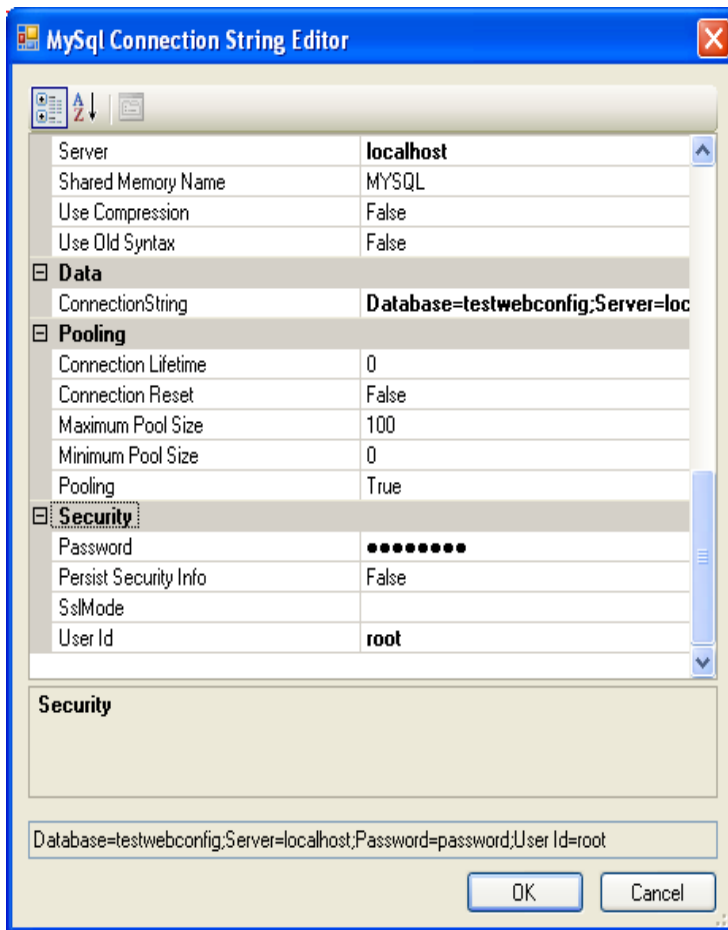

- A checkbox labeled "Use MySQL to manage my membership records" which is currently unchecked.
- A text box labeled "Name:" containing the character "/".
- A text box labeled "Description:" containing the text "MySQL default application".
- A text box labeled "Connection String:" which is empty, with an "Edit..." button to its right.
- A checkbox labeled "Autogenerate Schema" which is checked.
- A checkbox labeled "Write exceptions to event log" which is unchecked, with an "Advanced..." button to its right.

At the bottom of the dialog, there are three buttons: "Back", "Next", and "Cancel". The "Next" button is highlighted with a blue border.

This allows you to enable use of the MySQL Membership Provider. Click the check box to enable this. You can now enter the name of the application that you are creating the configuration for. You can also enter a description for the application.

You can then click the **Edit...** button to launch the Connection String Editor:

Figure 22.31. MySQL Website Configuration Tool - Connection String Editor

Note that if you have already defined a connection string for the providers manually in `web.config`, or previously using the tool, this will be automatically loaded and displayed, and can then be modified in this dialog.

You can also ensure that the necessary schemas are created automatically for you by selecting the Autogenerate Schema check box. These schemas are used to store membership information. The database used to storage is the one specified in the connection string.

You can also ensure that exceptions generated by the application will be written to the Windows event log by selecting the **Write exceptions to event log** check box.

Clicking the Advanced... button launches a dialog that enables you to set Membership Options. These options dictate such variables as password length required when a user signs up, whether the password is encrypted and whether the user can reset their password or not.

Figure 22.32. MySQL Website Configuration Tool - Advanced Options

Membership Options

Password Options

Minimum Required Password Length: 7

Min Required Non-alphanumeric Characters: 1

Password strength regular expression:

Password Format: Clear

User Options

Require Question/Answer Enable Password Reset

Requires Unique Email Enable Password Retrieval

Access Options

Maximum Invalid Password Attempts: 5

Password Attempt Window: 10

OK Cancel

Once information has been set up as required for configuration of the Membership Provider, the **Next** button can be clicked to display the Roles Provider screen:

Figure 22.33. MySQL Website Configuration Tool - Roles

The screenshot shows the 'Roles' configuration window. The title bar reads 'MySQL Website Configuration'. Below the title bar, the word 'Roles' is displayed in bold, followed by the instruction 'Set options for use with the role provider'. A gear icon is visible in the top right corner. The main area contains the following elements: a checked checkbox for 'Use MySQL to manage my roles'; a 'Name:' label with a text box containing '/'; a 'Description:' label with an empty text box; a 'Connection String:' label with a text box and an 'Edit...' button to its right; two unchecked checkboxes for 'Autogenerate Schema' and 'Write exceptions to event log'; and three buttons at the bottom: 'Back', 'Next', and 'Cancel'.

Again the connection string can be edited, a description added and Autogenerate Schema can be enabled before clicking **Next** to go to the Profiles Provider screen:

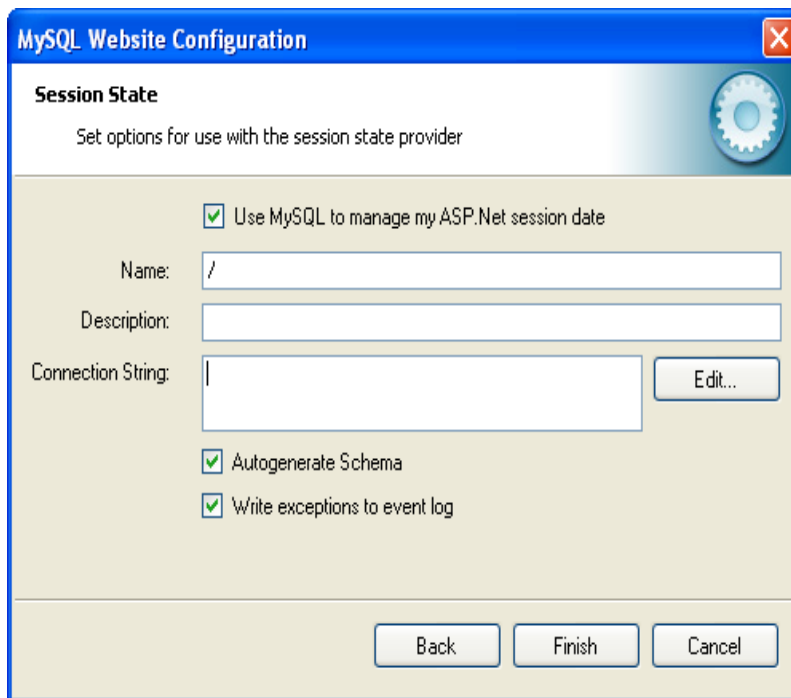

Figure 22.34. MySQL Website Configuration Tool - Profiles

The screenshot shows the 'Profiles' configuration window. The title bar reads 'MySQL Website Configuration'. Below the title bar, the word 'Profiles' is displayed in bold, followed by the instruction 'Set options for use with the profile provider'. A gear icon is visible in the top right corner. The main area contains the following elements: a checked checkbox for 'Use MySQL to manage my profiles'; a 'Name:' label with a text box containing '/'; a 'Description:' label with a text box containing 'Profiles'; a 'Connection String:' label with a text box and an 'Edit...' button to its right; a checked checkbox for 'Autogenerate Schema'; and three buttons at the bottom: 'Back', 'Finish', and 'Cancel'.

This screen display similar options to the previous screens.

Click **Next** to proceed to the Session State configuration page:

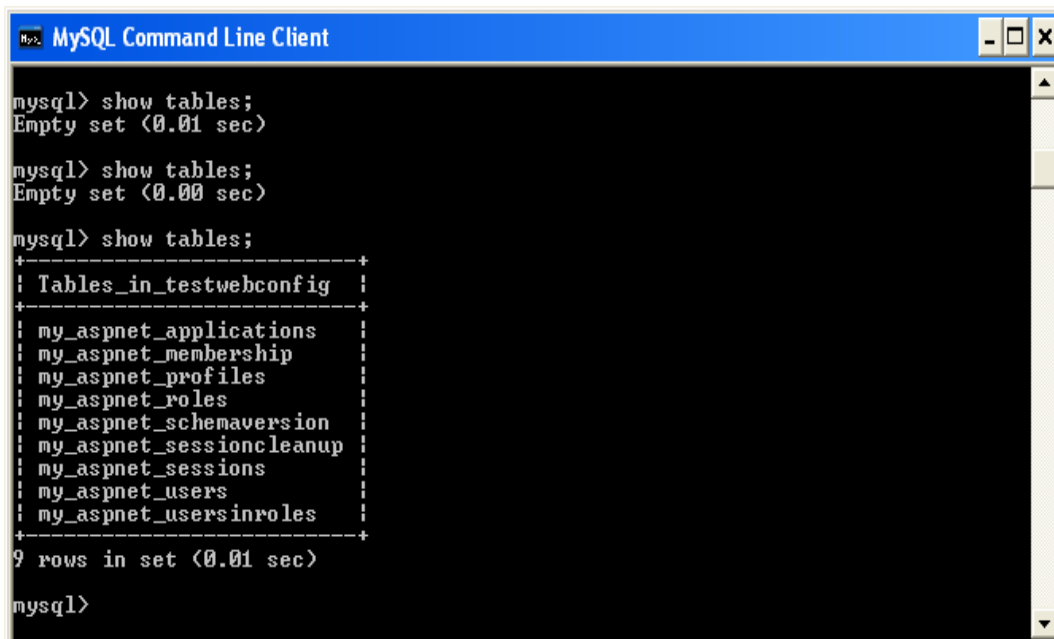

Figure 22.35. MySQL Website Configuration Tool - Session State

Once you have set up the Session State Provider as required, click **Finish** to exit the wizard.

At this point, select the **Authentication Type** to **From Internet**. Launch the ASP.NET Configuration Tool and select the Security tab. Click the **Select authentication type** link and ensure that the **From the internet** radio button is selected. You can now examine the database you created to store membership information. All the necessary tables will have been created for you:

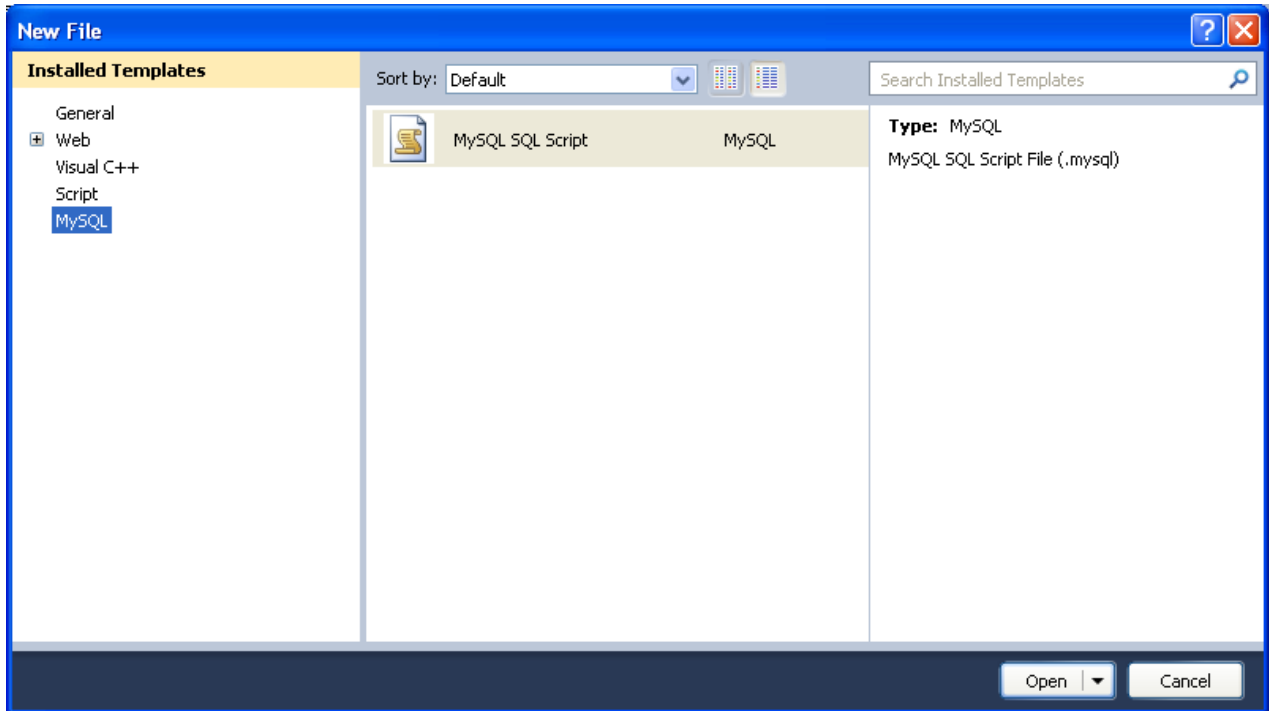

Figure 22.36. MySQL Website Configuration Tool - Tables

22.2.3.13. MySQL SQL Editor

MySQL Connector/Net 6.3.2 introduced a new MySQL SQL Editor. The easiest way to invoke the editor is by selecting the **New**, **File** menu item from the Visual Studio main menu. This displays the **New File** dialog:

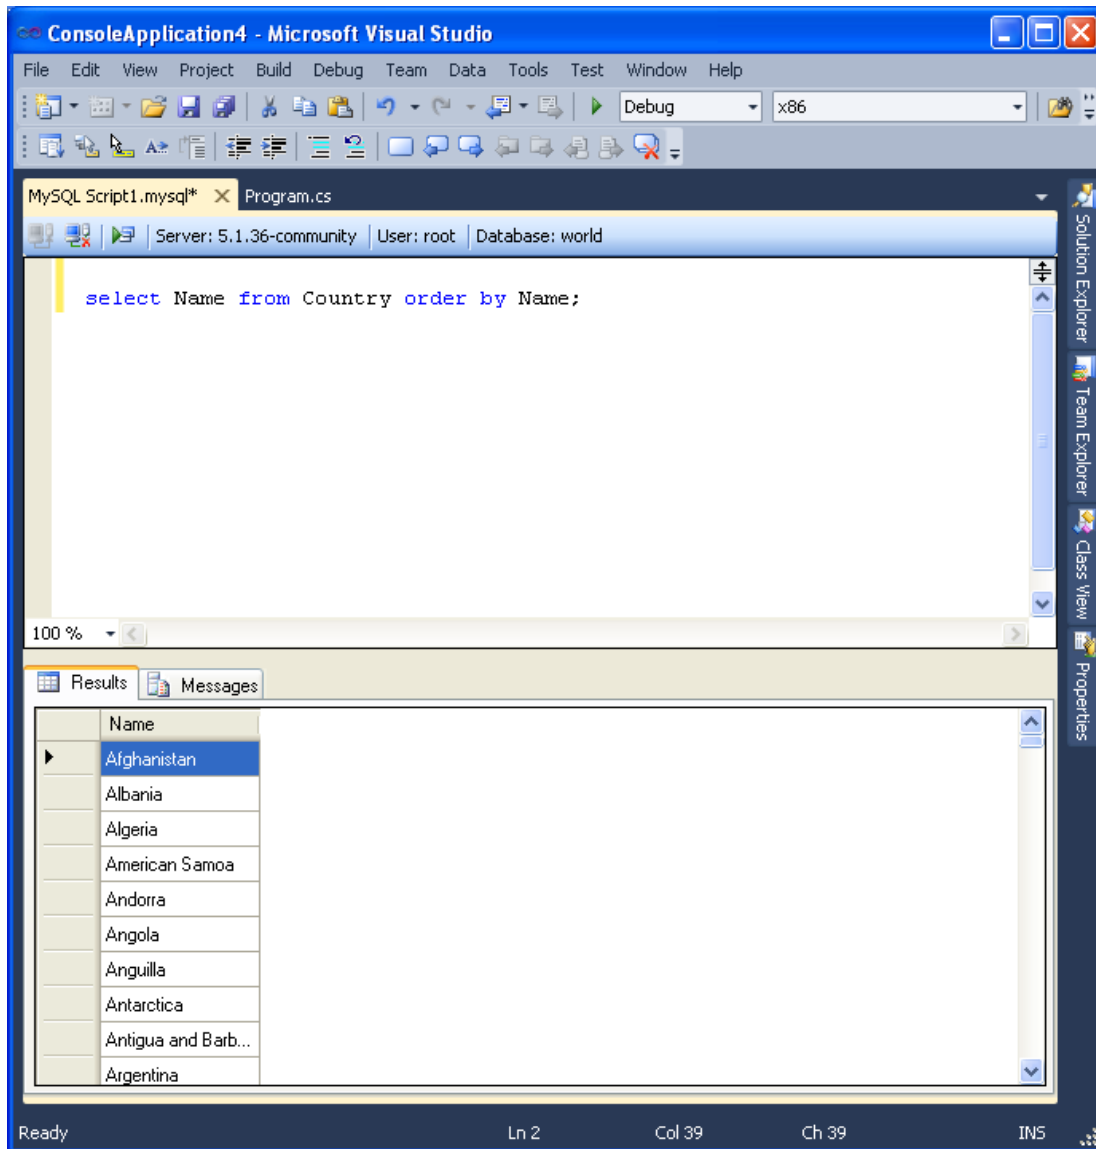

Figure 22.37. MySQL SQL Editor - New File

From the **New File** dialog, select the MySQL template, and then double-click the **MySQL SQL Script** document, or click the **Open** button.

The MySQL SQL Editor will be displayed. You can now enter SQL code as required, or connect to a MySQL server. Click the **Connect to MySQL** button in the MySQL SQL Editor toolbar. You can enter the connection details into the **Connect to MySQL** dialog that is displayed. You can enter the server name, user ID, password and database to connect to, or click the **Advanced** button to select other connection string options. Click the **Connect** button to connect to the MySQL server. To execute your SQL code against the server, click the **Run SQL** button on the toolbar.

Figure 22.38. MySQL SQL Editor - Query

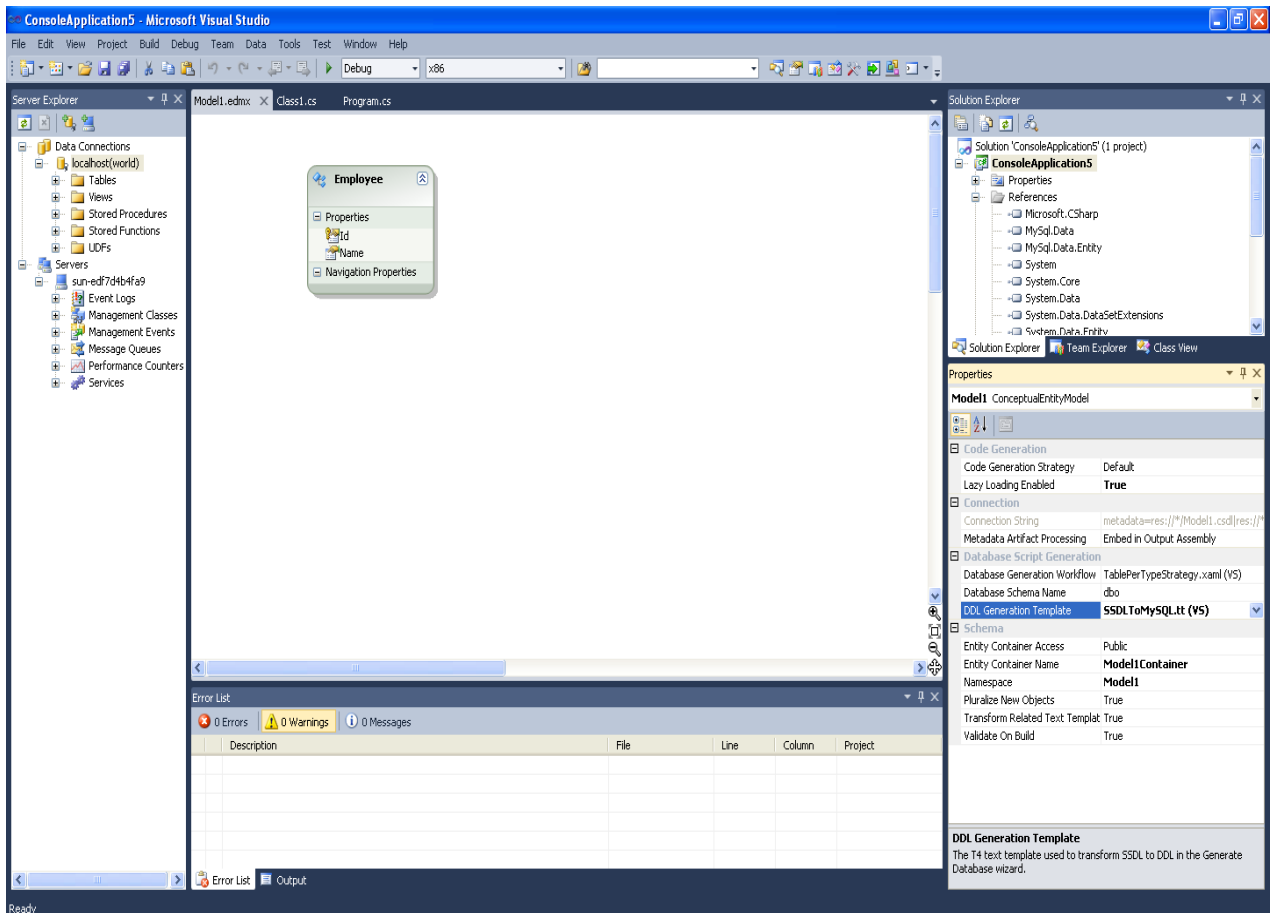

The results from any queries are displayed on the **Results** tab. Any errors are displayed on the **Messages** tab.

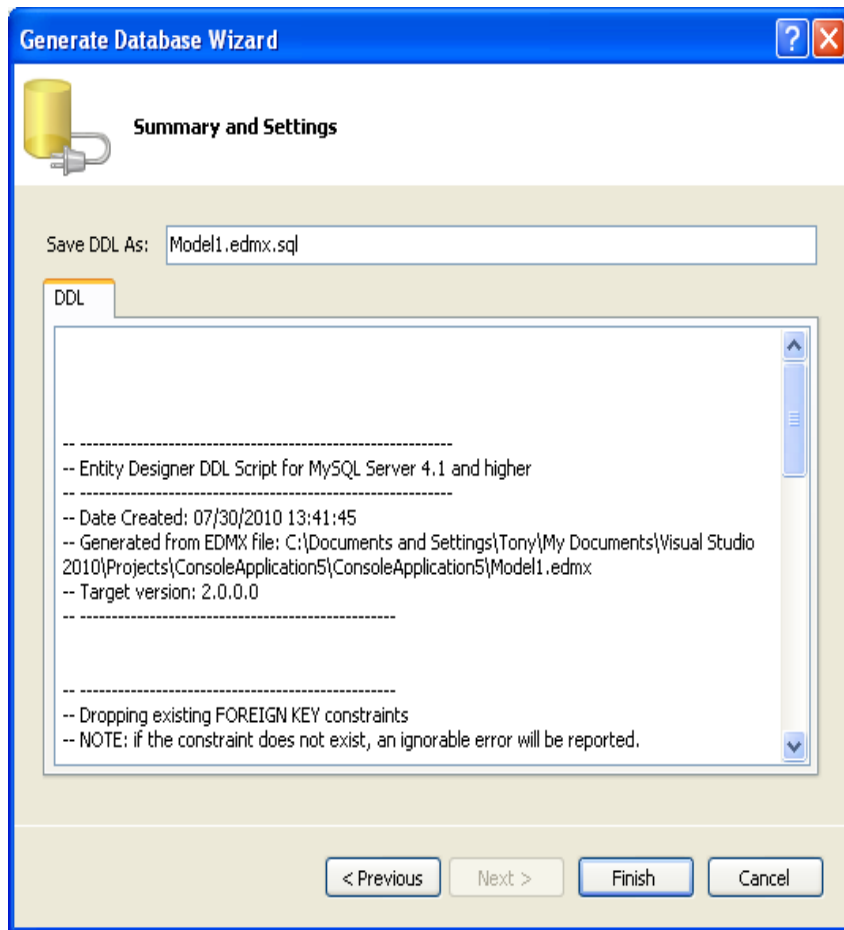

22.2.3.14. DDL T4 Template Macro

MySQL Connector/Net 6.3 introduced the ability to convert an Entity Framework model to MySQL **DDL** code. Starting with a blank model, you can develop an entity model in Visual Studio's designer. Once the model is created, you can select the model's properties, and in the Database Script Generation category of the model's properties, the property **DDL Generation** can be found. Select the value **SSDLToMySQL.tt(VS)** from the drop-down listbox.

Figure 22.39. DDL T4 Template Macro - Model Properties

Right-clicking the model design area displays a context-sensitive menu. Selecting **Generate Database from Model** from the menu displays the **Generate Database Wizard**. The wizard can then be used to generate MySQL DDL code.

Figure 22.40. DDL T4 Template Macro - Generate Database Wizard

22.2.4. Connector/Net Tutorials

The following tutorials illustrate how to develop MySQL programs using technologies such as Visual Studio, C#, ASP.NET, and the .NET and Mono frameworks. Work through the first tutorial to verify that you have the right software components installed and configured, then choose other tutorials to try depending on the features you intend to use in your applications.

22.2.4.1. Tutorial: An Introduction to Connector/Net Programming

This section provides a gentle introduction to programming with Connector/Net. The example code is written in C#, and is designed to work on both Microsoft .NET Framework and Mono.

This tutorial is designed to get you up and running with Connector/Net as quickly as possible, it does not go into detail on any particular topic. However, the following sections of this manual describe each of the topics introduced in this tutorial in more detail. In this tutorial you are encouraged to type in and run the code, modifying it as required for your setup.

This tutorial assumes you have MySQL and Connector/Net already installed. It also assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page.

**Note**

Before compiling the example code, make sure that you have added References to your project as required. The References required are [System](#), [System.Data](#) and [MySql.Data](#).

22.2.4.1.1. The MySqlConnection Object

For your Connector/Net application to connect to a MySQL database, it must establish a connection by using a [MySqlConnection](#) object.

The [MySqlConnection](#) constructor takes a connection string as one of its parameters. The connection string provides necessary information to make the connection to the MySQL database. The connection string is discussed more fully in [Section 22.2.5.1, "Connecting to MySQL Using Connector/Net"](#). For a list of supported connection string options, see [Section 22.2.6, "Connector/Net Connection String Options Reference"](#).

The following code shows how to create a connection object:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial1
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();
            // Perform database operations
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When the [MySqlConnection](#) constructor is invoked, it returns a connection object, which is used for subsequent database operations. Open the connection before any other operations take place. Before the application exits, close the connection to the database by calling [Close](#) on the connection object.

Sometimes an attempt to perform an [Open](#) on a connection object can fail, generating an exception that can be handled using standard exception handling code.

In this section you have learned how to create a connection to a MySQL database, and open and close the corresponding connection object.

22.2.4.1.2. The MySqlCommand Object

Once a connection has been established with the MySQL database, the next step is to carry out the desired database operations. This can be achieved through the use of the [MySqlCommand](#) object.

You will see how to create a [MySQLCommand](#) object. Once it has been created, there are three main methods of interest that you can call:

- **ExecuteReader** - used to query the database. Results are usually returned in a [MySQLDataReader](#) object, created by [ExecuteReader](#).
- **ExecuteNonQuery** - used to insert and delete data.
- **ExecuteScalar** - used to return a single value.

Once a [MySQLCommand](#) object has been created, you will call one of the above methods on it to carry out a database operation, such as perform a query. The results are usually returned into a [MySQLDataReader](#) object, and then processed, for example the results might be displayed. The following code demonstrates how this could be done.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial2
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            MySQLDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr[0]+" -- "+rdr[1]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When a connection has been created and opened, the code then creates a [MySQLCommand](#) object. Note that the SQL query to be executed is passed to the [MySQLCommand](#) constructor. The [ExecuteReader](#) method is then used to generate a [MySQLReader](#) object. The [MySQLReader](#) object contains the results generated by the SQL executed on the command object. Once the results have been obtained in a [MySQLReader](#) object, the results can be processed. In this case, the information is printed out by a [while](#) loop. Finally, the [MySQLReader](#) object is disposed of by running its [Close](#) method on it.

In the next example, you will see how to use the [ExecuteNonQuery](#) method.

The procedure for performing an `ExecuteNonQuery` method call is simpler, as there is no need to create an object to store results. This is because `ExecuteNonQuery` is only used for inserting, updating and deleting data. The following example illustrates a simple update to the `Country` table:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial3
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "INSERT INTO Country (Name, HeadOfState, Continent) VALUES ('Disneyland', 'Mickey Mouse', 'USA')";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            cmd.ExecuteNonQuery();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

The query is constructed, the command object created and the `ExecuteNonQuery` method called on the command object. You can access your MySQL database with the `mysql` command interpreter and verify that the update was carried out correctly.

Finally, you will see how the `ExecuteScalar` method can be used to return a single value. Again, this is straightforward, as a `MySqlDataReader` object is not required to store results, a simple variable will do. The following code illustrates how to use `ExecuteScalar`:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial4
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT COUNT(*) FROM Country";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            object result = cmd.ExecuteScalar();
            if (result != null)
            {
                Console.WriteLine(result);
            }
        }
    }
}
```

```
        int r = Convert.ToInt32(result);
        Console.WriteLine("Number of countries in the World database is: " + r);
    }

}
catch (Exception ex)
{
    Console.WriteLine(ex.ToString());
}

conn.Close();
Console.WriteLine("Done.");
}
}
```

This example uses a simple query to count the rows in the [Country](#) table. The result is obtained by calling [ExecuteScalar](#) on the command object.

22.2.4.1.3. Working with Decoupled Data

Previously, when using [MySqlDataReader](#), the connection to the database was continually maintained, unless explicitly closed. It is also possible to work in a manner where a connection is only established when needed. For example, in this mode, a connection could be established to read a chunk of data, the data could then be modified by the application as required. A connection could then be reestablished only if and when the application writes data back to the database. This decouples the working data set from the database.

This decoupled mode of working with data is supported by Connector/Net. There are several parts involved in allowing this method to work:

- **Data Set** - The Data Set is the area in which data is loaded to read or modify it. A [DataSet](#) object is instantiated, which can store multiple tables of data.
- **Data Adapter** - The Data Adapter is the interface between the Data Set and the database itself. The Data Adapter is responsible for efficiently managing connections to the database, opening and closing them as required. The Data Adapter is created by instantiating an object of the [MySqlDataAdapter](#) class. The [MySqlDataAdapter](#) object has two main methods: [Fill](#) which reads data into the Data Set, and [Update](#), which writes data from the Data Set to the database.
- **Command Builder** - The Command Builder is a support object. The Command Builder works in conjunction with the Data Adapter. When a [MySqlDataAdapter](#) object is created, it is typically given an initial [SELECT](#) statement. From this [SELECT](#) statement the Command Builder can work out the corresponding [INSERT](#), [UPDATE](#) and [DELETE](#) statements that would be required to update the database. To create the Command Builder, an object of the class [MySqlCommandBuilder](#) is created.

Each of these classes will now be discussed in more detail.

Instantiating a DataSet object

A [DataSet](#) object can be created simply, as shown in the following example code snippet:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
```

Although this creates the [DataSet](#) object, it has not yet filled it with data. For that, a Data Adapter is required.

Instantiating a MySqlDataAdapter object

The `MySqlDataAdapter` can be created as illustrated by the following example:

```
MySqlDataAdapter daCountry;  
...  
string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";  
daCountry = new MySqlDataAdapter (sql, conn);
```

Note, the `MySqlDataAdapter` is given the SQL specifying the data to work with.

Instantiating a `MySqlCommandBuilder` object

Once the `MySqlDataAdapter` has been created, it is necessary to generate the additional statements required for inserting, updating and deleting data. There are several ways to do this, but in this tutorial you will see how this can most easily be done with `MySqlCommandBuilder`. The following code snippet illustrates how this is done:

```
MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);
```

Note that the `MySqlDataAdapter` object is passed as a parameter to the command builder.

Filling the Data Set

To do anything useful with the data from your database, you need to load it into a Data Set. This is one of the jobs of the `MySqlDataAdapter` object, and is carried out with its `Fill` method. The following example code illustrates this:

```
DataSet dsCountry;  
...  
dsCountry = new DataSet();  
...  
daCountry.Fill(dsCountry, "Country");
```

Note the `Fill` method is a `MySqlDataAdapter` method, the Data Adapter knows how to establish a connection with the database and retrieve the required data, and then populates the Data Set when the `Fill` method is called. The second parameter "Country" is the table in the Data Set to update.

Updating the Data Set

The data in the Data Set can now be manipulated by the application as required. At some point, changes to data will need to be written back to the database. This is achieved through a `MySqlDataAdapter` method, the `Update` method.

```
daCountry.Update(dsCountry, "Country");
```

Again, the Data Set and the table within the Data Set to update are specified.

Working Example

The interactions between the `DataSet`, `MySqlDataAdapter` and `MySqlCommandBuilder` classes can be a little confusing, so their operation can perhaps be best illustrated by working code.

In this example, data from the World database is read into a Data Grid View control. Here, the data can be viewed and changed before clicking an update button. The update button then activates code to write changes back to the database. The code uses the principles explained above. The application was built using the Microsoft Visual Studio to place and create the user interface controls, but the main code that uses the key classes described above is shown below, and is portable.

```
using System;
```

```
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Linq;
using System.Text;
using System.Windows.Forms;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace WindowsFormsApplication5
{
    public partial class Form1 : Form
    {
        MySqlDataAdapter daCountry;
        DataSet dsCountry;

        public Form1()
        {
            InitializeComponent();
        }

        private void Form1_Load(object sender, EventArgs e)
        {
            string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                label2.Text = "Connecting to MySQL...";

                string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
                daCountry = new MySqlDataAdapter (sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);

                dsCountry = new DataSet();
                daCountry.Fill(dsCountry, "Country");
                dataGridView1.DataSource = dsCountry;
                dataGridView1.DataMember = "Country";
            }
            catch (Exception ex)
            {
                label2.Text = ex.ToString();
            }
        }

        private void button1_Click(object sender, EventArgs e)
        {
            daCountry.Update(dsCountry, "Country");
            label2.Text = "MySQL Database Updated!";
        }
    }
}
```

The application running is shown below:

Figure 22.41. World Database Application

22.2.4.1.4. Working with Parameters

This part of the tutorial shows you how to use parameters in your Connector/Net application.

Although it is possible to build SQL query strings directly from user input, this is not advisable as it does not prevent erroneous or malicious information being entered. It is safer to use parameters as they will be processed as field data only. For example, imagine the following query was constructed from user input:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = "+user_continent;
```

If the string `user_continent` came from a Text Box control, there would potentially be no control over the string entered by the user. The user could enter a string that generates a run time error, or in the worst case actually harms the system. When using parameters it is not possible to do this because a parameter is only ever treated as a field parameter, rather than an arbitrary piece of SQL code.

The same query written user a parameter for user input would be:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = @Continent";
```

Note that the parameter is preceded by an '@' symbol to indicate it is to be treated as a parameter.

As well as marking the position of the parameter in the query string, it is necessary to add a parameter to the Command object. This is illustrated by the following code snippet:

```
cmd.Parameters.AddWithValue("@Continent", "North America");
```

In this example the string "North America" is supplied as the parameter value statically, but in a more practical example it would come from a user input control.

A further example illustrates the complete process:

```

using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial5
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent=@Continent";
            MySqlCommand cmd = new MySqlCommand(sql, conn);

            Console.WriteLine("Enter a continent e.g. 'North America', 'Europe': ");
            string user_input = Console.ReadLine();

            cmd.Parameters.AddWithValue("@Continent", user_input);

            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr["Name"]+" --- "+rdr["HeadOfState"]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}

```

In this part of the tutorial you have see how to use parameters to make your code more secure.

22.2.4.1.5. Working with Stored Procedures

This section illustrates how to work with stored procedures. Putting database-intensive operations into stored procedures lets you define an API for your database application. You can reuse this API across multiple applications and multiple programming languages. This technique avoids duplicating database code, saving time and effort when you make updates due to schema changes, tune the performance of queries, or add new database operations for logging, security, and so on. Before working through this tutorial, familiarize yourself with the [CREATE PROCEDURE](#) and [CREATE FUNCTION](#) statements that create different kinds of stored routines.

For the purposes of this tutorial, you will create a simple stored procedure to see how it can be called from Connector/Net. In the MySQL Client program, connect to the World database and enter the following stored procedure:

```

DELIMITER //
CREATE PROCEDURE country_hos
(IN con CHAR(20))
BEGIN
    SELECT Name, HeadOfState FROM Country
    WHERE Continent = con;

```

```
END //  
DELIMITER ;
```

Test that the stored procedure works as expected by typing the following into the `mysql` command interpreter:

```
CALL country_hos('Europe');
```

Note that The stored routine takes a single parameter, which is the continent to restrict your search to.

Having confirmed that the stored procedure is present and correct, you can see how to access it from Connector/Net.

Calling a stored procedure from your Connector/Net application is similar to techniques you have seen earlier in this tutorial. A `MySqlCommand` object is created, but rather than taking an SQL query as a parameter, it takes the name of the stored procedure to call. Set the `MySqlCommand` object to the type of stored procedure, as shown by the following code snippet:

```
string rtn = "country_hos";  
MySqlCommand cmd = new MySqlCommand(rtn, conn);  
cmd.CommandType = CommandType.StoredProcedure;
```

In this case, the stored procedure requires you to pass a parameter. This can be achieved using the techniques seen in the previous section on parameters, [Section 22.2.4.1.4, "Working with Parameters"](#), as shown in the following code snippet:

```
cmd.Parameters.AddWithValue("@con", "Europe");
```

The value of the parameter `@con` could more realistically have come from a user input control, but for simplicity it is set as a static string in this example.

At this point, everything is set up and you can call the routine using techniques also learned in earlier sections. In this case, the `ExecuteReader` method of the `MySqlCommand` object is used.

Complete working code for the stored procedure example is shown below:

```
using System;  
using System.Data;  
  
using MySql.Data;  
using MySql.Data.MySqlClient;  
  
public class Tutorial6  
{  
    public static void Main()  
    {  
        string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";  
        MySqlConnection conn = new MySqlConnection(connStr);  
        try  
        {  
            Console.WriteLine("Connecting to MySQL...");  
            conn.Open();  
  
            string rtn = "country_hos";  
            MySqlCommand cmd = new MySqlCommand(rtn, conn);  
            cmd.CommandType = CommandType.StoredProcedure;  
  
            cmd.Parameters.AddWithValue("@con", "Europe");  
  
            MySqlDataReader rdr = cmd.ExecuteReader();  
            while (rdr.Read())  
            {  
                Console.WriteLine(rdr[0] + " --- " + rdr[1]);  
            }  
            rdr.Close();  
        }  
    }  
}
```

```
    }  
    catch (Exception ex)  
    {  
        Console.WriteLine(ex.ToString());  
    }  
  
    conn.Close();  
    Console.WriteLine("Done.");  
}  
}
```

In this section, you have seen how to call a stored procedure from Connector/Net. For the moment, this concludes our introductory tutorial on programming with Connector/Net.

22.2.4.2. Tutorial: MySQL Connector/Net ASP.NET Membership and Role Provider

Many web sites feature the facility for the user to create a user account. They can then log into the web site and enjoy a personalized experience. This requires that the developer creates database tables to store user information, along with code to gather and process this data. This represents a burden on the developer, and there is the possibility for security issues to creep into the developed code. However, ASP.NET 2.0 introduced the Membership system. This system is designed around the concept of Membership, Profile and Role Providers, which together provide all of the functionality to implement a user system, that previously would have to have been created by the developer from scratch.

Currently, MySQL Connector/Net provides Membership, Role, Profile and Session State Providers.

This tutorial shows you how to set up your ASP.NET web application to use the MySQL Connector/Net Membership and Role Providers. It assumes that you have MySQL Server installed, along with MySQL Connector/Net and Microsoft Visual Studio. This tutorial was tested with MySQL Connector/Net 6.0.4 and Microsoft Visual Studio 2008 Professional Edition. It is recommended you use 6.0.4 or above for this tutorial.

1. Create a new database in the MySQL Server using the MySQL Command Line Client program ([mysql](#)), or other suitable tool. It does not matter what name is used for the database, but record it. You specify it in the connection string constructed later in this tutorial. This database contains the tables, automatically created for you later, used to store data about users and roles.
2. Create a new ASP.NET Web Site in Visual Studio. If you are not sure how to do this, refer to [Section 22.2.4.6, "Tutorial: Databinding in ASP.NET using LINQ on Entities"](#), which demonstrates how to create a simple ASP.NET web site.
3. Add References to [MySQL.Data](#) and [MySQL.Web](#) to the web site project.
4. Locate the [machine.config](#) file on your system, which is the configuration file for the .NET Framework.
5. Search the [machine.config](#) file to find the membership provider [MySQLMembershipProvider](#).
6. Add the attribute `autogenerateschema="true"`. The appropriate section should now resemble the following (note: for the sake of brevity some information has been excluded):

```
<membership>  
  <providers>  
    <add name="AspNetSqlMembershipProvider"  
      type="System.Web.Security.SqlMembershipProvider"  
      ...  
      connectionStringName="LocalSqlServer"  
      ... />  
    <add name="MySQLMembershipProvider"  
      autogenerateschema="true"  
      type="MySQL.Web.Security.MySQLMembershipProvider, MySQL.Web, Version=6.0.4.0, Culture=neutral, Pub
```

```
connectionStringName="LocalMySQLServer"
... />
</providers>
</membership>
```

Note that the name for the connection string to be used to connect to the server that contains the membership database is `LocalMySQLServer`.

The `autogenerateschema="true"` attribute will cause MySQL Connector/Net to silently create, or upgrade, the schema on the database server, to contain the required tables for storing membership information.

7. It is now necessary to create the connection string referenced in the previous step. Load the web site's `web.config` file into Visual Studio.
8. Locate the section marked `<connectionStrings>`. Add the following connection string information:

```
<connectionStrings>
  <remove name="LocalMySQLServer" />
  <add name="LocalMySQLServer"
    connectionString="Datasource=localhost;Database=users;uid=root;pwd=password;"
    providerName="MySql.Data.MySqlClient" />
</connectionStrings>
```

The database specified is the one created in the first step. You could alternatively have used an existing database.

9. At this point build the solution to ensure no errors are present. This can be done by selecting **Build**, **Build Solution** from the main menu, or pressing **F6**.
10. ASP.NET supports the concept of locally and remotely authenticated users. With local authentication the user is validated using their Windows credentials when they attempt to access the web site. This can be useful in an Intranet environment. With remote authentication, a user is prompted for their login details when accessing the web site, and these credentials are checked against the membership information stored in a database server such as MySQL Server. You will now see how to choose this form of authentication.

Start the ASP.NET Web Site Administration Tool. This can be done quickly by clicking the small hammer/Earth icon in the Solution Explorer. You can also launch this tool by selecting **Website**, **ASP.NET Configuration** from the main menu.

11. In the ASP.NET Web Site Administration Tool click the **Security** tab.
12. Now click the **User Authentication Type** link.
13. Select the **From the internet** radio button. The web site will now need to provide a form to allow the user to enter their login details. These will be checked against membership information stored in the MySQL database.

Figure 22.42. Authentication Type

The screenshot shows the ASP.NET Web Site Administration Tool interface. The title bar reads "ASP.NET Web Site Administration Tool". Below the title bar are four tabs: "Home", "Security", "Application", and "Provider". The "Security" tab is selected. The main content area asks "How will users access your site?" and provides two radio button options:

- From the internet**
Select this option if users will access your web site from the public internet. Users will be required to log on using a web form. The site will use forms authentication to identify users according to user information that you store in a database.
- From a local network**
Select this option if users will access your web site only from a private local network. The site will use built-in Microsoft Windows authentication to identify users. Users with a valid Windows user name and password will be able to access your site.

14. You now need to specify the Role and Membership Provider to be used. Click the **Provider** tab.
15. Click the **Select a different provider for each feature (advanced)** link.
16. Now select the **MySQLMembershipProvider** and the **MySQLRoleProvider** radio buttons.

Figure 22.43. Select Membership and Role Provider

The screenshot shows the ASP.NET Web Site Administration Tool interface with the "Provider" tab selected. The main content area says "Use this page to select a provider for each feature." There are two sections:

Membership Provider

- AspNetSqlMembershipProvider [Test](#)
- MySQLMembershipProvider

Role Provider

- AspNetSqlRoleProvider [Test](#)
- AspNetWindowsTokenRoleProvider
- MySQLRoleProvider

17. In Visual Studio, rebuild the solution by selecting **Build**, **Rebuild Solution** from the main menu.
18. Check that the necessary schema has been created. This can be achieved using the `mysql` command interpreter.

Figure 22.44. Membership and Role Provider Tables

```
MySQL Command Line Client
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| test |
| users |
| world |
+-----+
5 rows in set (0.01 sec)

mysql> show tables;
+-----+
| Tables_in_users |
+-----+
| my_aspnet_applications |
| my_aspnet_membership |
| my_aspnet_profiles |
| my_aspnet_roles |
| my_aspnet_schemaversion |
| my_aspnet_users |
| my_aspnet_usersinroles |
+-----+
7 rows in set (0.00 sec)

mysql>
```

19. Assuming all is present and correct, you can now create users and roles for your web application. The easiest way to do this is with the ASP.NET Web Site Administration Tool. However, many web applications contain their own modules for creating roles and users. For simplicity, the ASP.NET Web Site Administration Tool will be used in this tutorial.
20. In the ASP.NET Web Site Administration Tool, click the **Security** tab. Now that both the Membership and Role Provider are enabled, you will see links for creating roles and users. Click the **Create or Manage Roles** link.

Figure 22.45. Security Tab

ASP.NET Web Site Administration Tool

Home Security Application Provider

You can use the Web Site Administration Tool to manage all the security settings for your application. You can set up users and passwords (authentication), create roles (groups of users), and create permissions (rules for controlling access to parts of your application).

By default, user information is stored in a Microsoft SQL Server Express database in the Data folder of your Web site. If you want to store user information in a different database, use the Provider tab to select a different provider.

[Use the security Setup Wizard to configure security step by step.](#)

Click the links in the table to manage the settings for your application.

| Users | Roles | Access Rules |
|---|---|--|
| Existing users: 1 Create user Manage users Select authentication type | Existing roles: 2 Disable Roles Create or Manage roles | Create access rules Manage access rules |

21. You can now enter the name of a new Role and click **Add Role** to create the new Role. Create new Roles as required.
22. Click the **Back** button.
23. Click the **Create User** link. You can now fill in information about the user to be created, and also allocate that user to one or more Roles.

Figure 22.46. Create User

ASP.NET Web Site Administration Tool

Home Security Application Provider

Add a user by entering the user's ID, password, and e-mail address on this page.

Create User

Sign Up for Your New Account

User Name: johndoe

Password: ●●●●●●●●

Confirm Password: ●●●●●●●●

E-mail: johndoe@example.com

Security Question: Statler and ...

Security Answer: Waldorf

Roles

Select roles for this user:

Visitors

Admins

Active User

24. Using the `mysql` command interpreter, you can check that your database has been correctly populated with the Membership and Role data.

Figure 22.47. Membership and Roles Table Contents

```

mysql> select * from my_aspnet_users;
+----+-----+-----+-----+-----+
| id | applicationId | name | isAnonymous | lastActivityDate |
+----+-----+-----+-----+-----+
| 1 | 1 | johndoe | 0 | 2009-07-14 17:17:25 |
+----+-----+-----+-----+-----+
1 row in set (0.01 sec)

mysql> select * from my_aspnet_roles;
+----+-----+-----+
| id | applicationId | name |
+----+-----+-----+
| 1 | 1 | Visitors |
| 2 | 1 | Admins |
+----+-----+-----+
2 rows in set (0.00 sec)

mysql>

```

In this tutorial, you have seen how to set up the MySQL Connector/Net Membership and Role Providers for use in your ASP.NET web application.

22.2.4.3. Tutorial: MySQL Connector/Net ASP.NET Session State Provider

MySQL Connector/Net from version 6.1 has included a MySQL Session State Provider. This provider enables you to store session state in a MySQL database. The following tutorial shows you how to prepare to use the MySQL Session State Provider, and then store session data into the MySQL database. This tutorial uses Microsoft Visual Studio 2008 Professional Edition, MySQL Connector/Net 6.1.1 and MySQL Server 5.1. This tutorial also assumes you have created an empty database, for example `test`, where you will store session data. You could do this using the `mysql` command interpreter.

1. In Visual Studio, create a new ASP.NET web site. If you are not sure how to do this, refer to the tutorial [Section 22.2.4.6, "Tutorial: Databinding in ASP.NET using LINQ on Entities"](#), which demonstrates how to do this.
2. Launch the MySQL Website Configuration tool. Due to a bug in 6.1.1, this may not appear unless you are connected to a server in the Server Explorer. If you are unfamiliar with the MySQL Website Configuration tool, consider first working through the tutorial in [Section 22.2.3.12, "MySQL Website Configuration Tool"](#).
3. Navigate through the wizard to the Session State page. Make sure the check box **Use MySQL to manage my ASP.NET session data** is selected.
4. On the same page, configure the connection string to the database that will contain your session data. If this database is empty, MySQL Connector/Net will create the schema required to store session data.
5. Ensure that the check box **Autogenerate Schema** is selected so that MySQL Connector/Net will create the schema in your database to store the session data correctly.
6. Enter the name of your application.
7. Click **Finish**. The MySQL Website Configuration tool will now update your application's `web.config` file with information about the connection string and default providers to be used. In this case, we have selected the MySQL Session State Provider.

At this point, you are ready to use the MySQL database to store session data. To test that the set up has worked, you can write a simple program that uses session variables.

1. Open `Default.aspx.cs`. In the `Page_Load` method, add the following code:

```
Session["SessionVariable1"] = "Test string";
```

2. Build your solution.
3. Run the solution (without debugging). When the application runs, the provider will autogenerate tables required in the database you chose when setting up the application.
4. Check that the schema was in fact created. Using the MySQL Command Line Client use the target database and then type `SHOW TABLES;`. You will see that MySQL Connector/Net has created the required schema automatically, as we selected this to happen in the MySQL Website Configuration tool.
5. Now view the contents of these tables by typing `SELECT * FROM my_aspnet_sessions;` in the `mysql` command interpreter. This will display the session data our application used. Note that this is stored in binary format so some data may not display as expected.

At this point, you have installed the Session State Provider and carried out a preliminary test of the installation. You will now work a bit more with the Session State Provider.

In this part of the tutorial, you will set and retrieve a session variable. You can work with your existing project.

1. Select the `Default.aspx` and switch to Design View. Add a text box and three buttons. Change the text property for the buttons to “Store Session Variable”, “Clear Textbox”, and “Show Session Variable”. These will be `Button1`, `Button2` and `Button3` respectively. Build your solution to ensure that no errors have been introduced.
2. Still in the Design View, double-click `Button1`. Now to the `Button1_Click` event handler add code some the handler resembles the following:

```
protected void Button1_Click(object sender, EventArgs e)
{
    Session["SessionString"] = TextBox1.Text;
}
```

You have created a new Session variable accessed using the key “SessionString”. This will be set to the text that was entered into the text box when `Button1` is clicked.

3. In Design View, double-click `Button2` to add its click event handler. This button needs to clear text from the text box. The code to do this is as follows:

```
protected void Button2_Click(object sender, EventArgs e)
{
    TextBox1.Text = "";
}
```

The code simply assigns an empty string to the `Text` property of the text box.

4. In the Design View double-click `Button3` and modify the click handler as follows:

```
protected void Button3_Click(object sender, EventArgs e)
{
    TextBox1.Text = (String)Session["SessionString"];
}
```

This will retrieve the session string and display it in the text box.

5. Now modify the `Page_Load` method as follows:

```
protected void Page_Load(object sender, EventArgs e)
{
    if (!IsPostBack)
    {
        TextBox1.Text = "Enter some text";
    }
}
```

This ensures that when the page loads the text box `Text` property is reset.

6. Ensure that the solution is saved and then rebuild the solution.
7. Run the solution without debugging.
8. The form will be displayed. Enter some text into the text box. Now click `Store Session Variable`. At this point you have stored the string in a session variable.
9. Now click `Clear Text` to clear the text box.
10. Now click `Show Session Variable` to retrieve and display the session variable.
11. Refresh the page to destroy the form and display a new form.
12. Click `Show Session Variable` the text box will display the stored session variable, demonstrating that the refreshing the page does not destroy the session variable.

This illustrates that the session state data is not destroyed when a page is reloaded.

22.2.4.4. Tutorial: MySQL Connector/Net ASP.NET Profile Provider

This tutorial shows you how to use the MySQL Profile Provider to store user profile information in a MySQL database. The tutorial uses MySQL Connector/Net 6.1.1, MySQL Server 5.1 and Microsoft Visual Studio 2008 Professional Edition.

Many modern web sites allow the user to create a personal profile. This requires a significant amount of code, but ASP.NET reduces this considerable by including the functionality in its Profile classes. The Profile Provider provides an abstraction between these classes and a data source. The MySQL Profile Provider enables profile data to be stored in a MySQL database. This enables the profile properties to be written to a persistent store, and be retrieved when required. The Profile Provider also enables profile data to be managed effectively, for example it enables profiles that have not been accessed since a specific date to be deleted.

The following steps show you how you can select the MySQL Profile Provider.

1. Create a new ASP.NET web project.
2. Select the MySQL Website Configuration tool. Due to a bug in 6.1.1 you may have to first connect to a server in Server Explorer before the tool's icon will display in the toolbar of the Solution Explorer.
3. In the MySQL Website Configuration tool navigate through the tool to the Profiles page.
4. Select the **Use MySQL to manage my profiles** check box.
5. Select the **Autogenerate Schema** check box.
6. Click the **Edit...** button and configure a connection string for the database that will be used to store user profile information.
7. Navigate to the last page of the tool and click **Finish** to save your changes and exit the tool.

At this point you are now ready to start using the MySQL Profile Provider. With the following steps you can carry out a preliminary test of your installation.

1. Open your `web.config` file.
2. Add a simple profile such as the following:

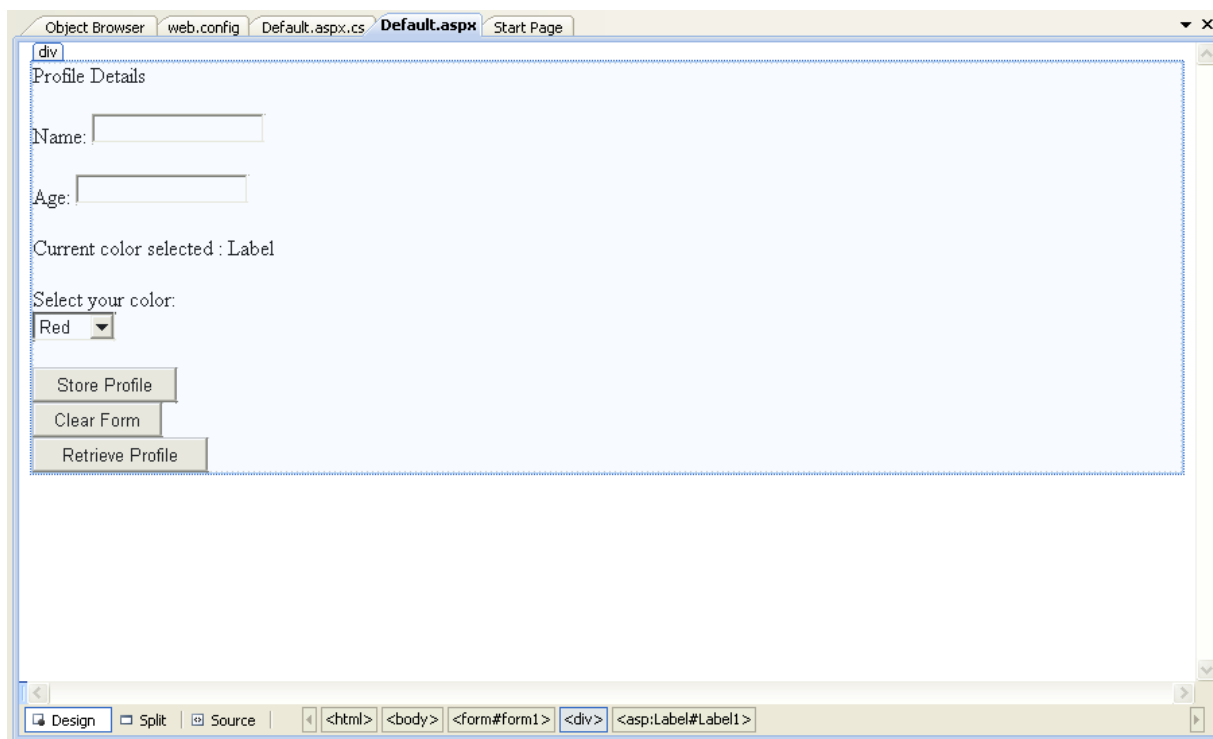

```
<system.web>
  <anonymousIdentification enabled="true"/>
  <profile defaultProvider="MySQLProfileProvider">
    ...
    <properties>
      <add name="Name" allowAnonymous="true"/>
      <add name="Age" allowAnonymous="true" type="System.UInt16"/>
      <group name="UI">
        <add name="Color" allowAnonymous="true" defaultValue="Blue"/>
        <add name="Style" allowAnonymous="true" defaultValue="Plain"/>
      </group>
    </properties>
  </profile>
  ...
```

Note that `anonymousIdentification` has been set to true. This enables users who have not been authenticated to use profiles. They are identified by a GUID in a cookie rather than by user name.

Now that the simple profile has been defined in `web.config`, the next step is to write some code to test the profile.

1. In Design View design a simple page with the following controls:

Figure 22.48. Simple Profile Application

These will allow the user to enter some profile information. The user can also use the buttons to save their profile, clear the page, and restore their profile data.

2. In the Code View add code as follows:

```
...
protected void Page_Load(object sender, EventArgs e)
{
    if (!IsPostBack)
    {
        TextBox1.Text = Profile.Name;
        TextBox2.Text = Profile.Age.ToString();
        Label1.Text = Profile.UI.Color;
    }
}

// Store Profile
protected void Button1_Click(object sender, EventArgs e)
{
    Profile.Name = TextBox1.Text;
    Profile.Age = UInt16.Parse(TextBox2.Text);
}

// Clear Form
protected void Button2_Click(object sender, EventArgs e)
{
    TextBox1.Text = "";
    TextBox2.Text = "";
    Label1.Text = "";
}

// Retrieve Profile
```

```
protected void Button3_Click(object sender, EventArgs e)
{
    TextBox1.Text = Profile.Name;
    TextBox2.Text = Profile.Age.ToString();
    Label1.Text = Profile.UI.Color;
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    Profile.UI.Color = DropDownList1.SelectedValue;
}
...
```

3. Save all files and build the solution to check that no errors have been introduced.
4. Run the application.
5. Enter your name, age and select a color from the listbox. Now store this information in your profile by clicking **Store Profile**. Note that if you do not select a color from the listbox your profile will use the default color **Blue** that was specified in the `web.config` file.
6. Click **Clear Form** to clear text from the textboxes and the label that displays your chosen color.
7. Now click **Retrieve Profile** to restore your profile data from the MySQL database.
8. Now exit the browser to terminate the application.
9. Run the application again. Note that when the page loads your profile information is restored from the MySQL database.

In this tutorial you have seen how to using the MySQL Profile Provider with MySQL Connector/Net.

22.2.4.5. Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source

In this tutorial you will learn how to create a Windows Forms Data Source from an Entity in an Entity Data Model. This tutorial assumes that you have installed the World example database, which can be downloaded from the [MySQL Documentation page](#). You can also find details on how to install the database on the same page. It will also be convenient for you to create a connection to the World database after it is installed. For instructions on how to do this see [Section 22.2.3.1, "Making a Connection"](#).

Creating a new Windows Forms application

The first step is to create a new Windows Forms application.

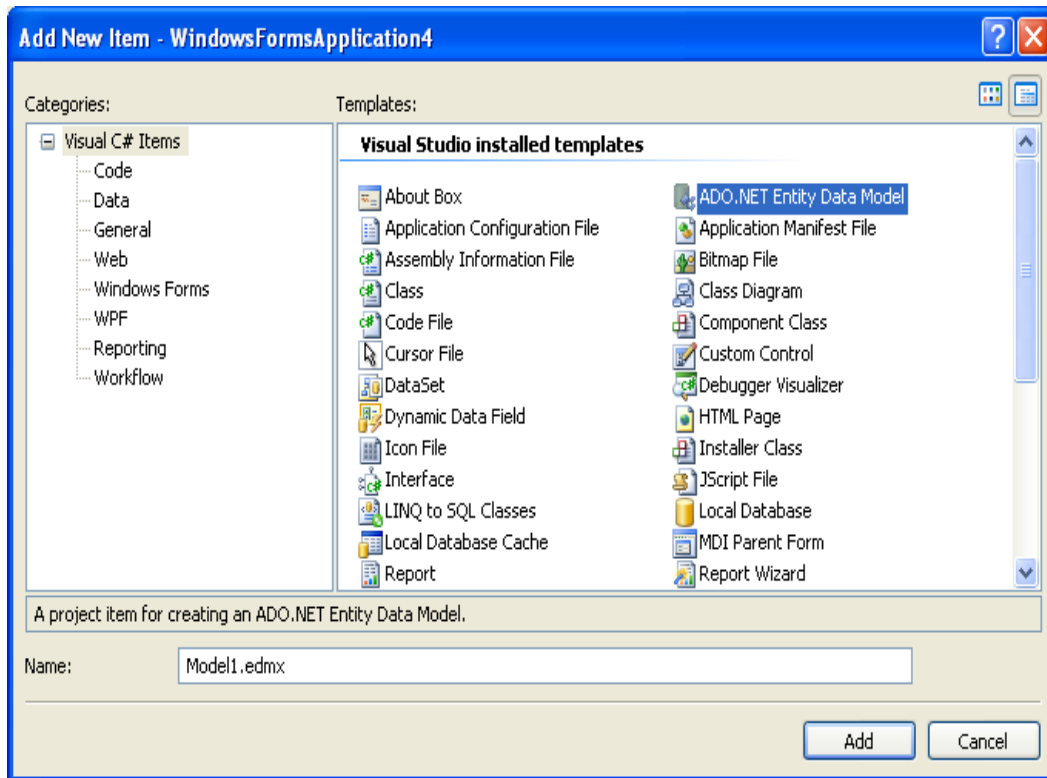

1. In Visual Studio, select **File, New, Project** from the main menu.
2. Choose the **Windows Forms Application** installed template. Click **OK**. The solution is created.

Adding an Entity Data Model

You will now add an Entity Data Model to your solution.

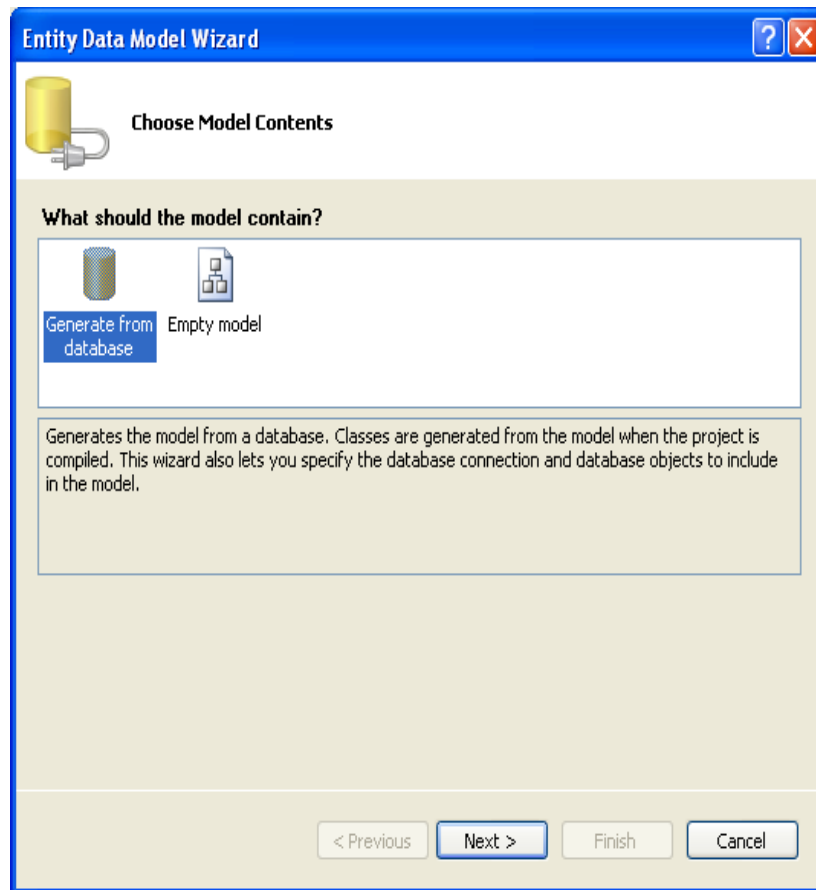

1. In the Solution Explorer, right-click your application and select **Add, New Item...**. From **Visual Studio installed templates** select **ADO.NET Entity Data Model**. Click **Add**.

Figure 22.49. Add Entity Data Model

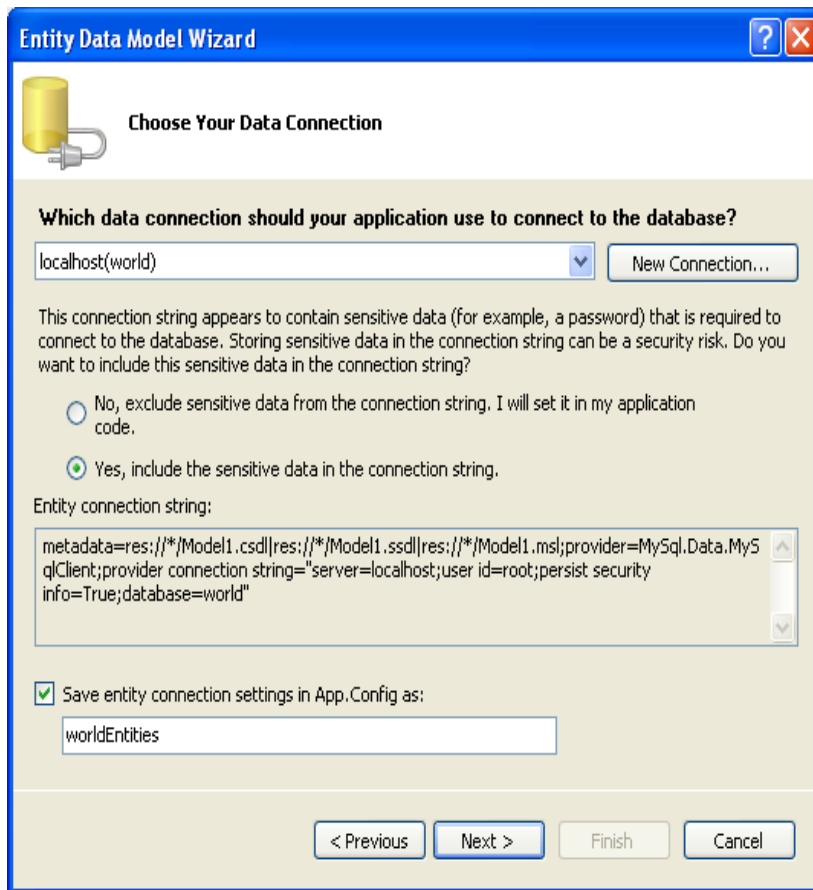

2. You will now see the Entity Data Model Wizard. You will use the wizard to generate the Entity Data Model from the world example database. Select the icon **Generate from database**. Click **Next**.

Figure 22.50. Entity Data Model Wizard Screen 1

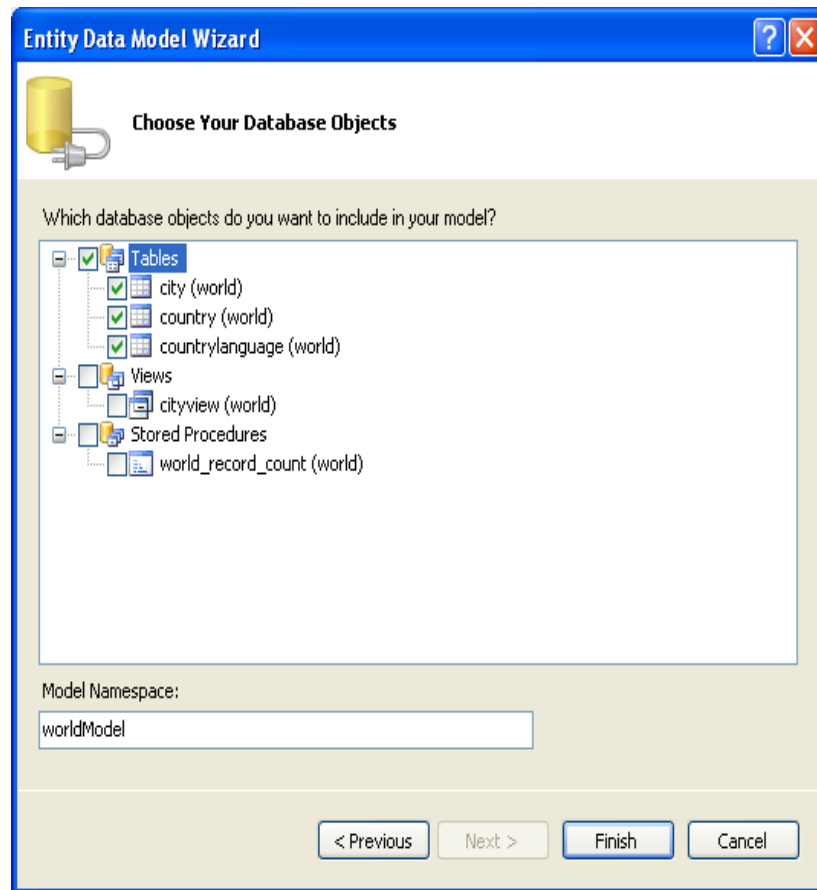

3. You can now select the connection you made earlier to the World database. If you have not already done so, you can create the new connection at this time by clicking **New Connection...**. For further instructions on creating a connection to a database see [Section 22.2.3.1, "Making a Connection"](#).

Figure 22.51. Entity Data Model Wizard Screen 2

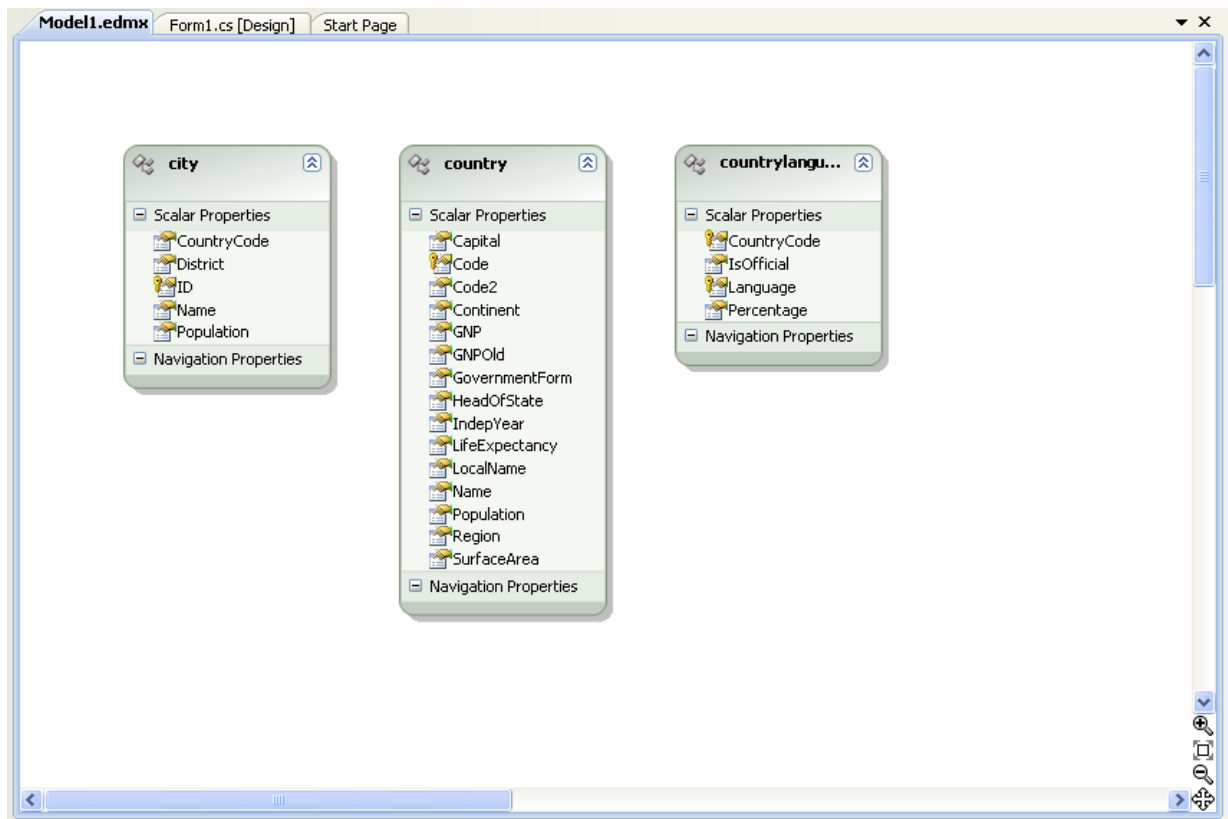

4. Make a note of the entity connection settings to be used in App.Config, as these will be used later to write the necessary control code.
5. Click **Next**.
6. The Entity Data Model Wizard connects to the database. You are then presented with a tree structure of the database. From this you can select the object you would like to include in your model. If you had created Views and Stored Routines these will be displayed along with any tables. In this example you just need to select the tables. Click **Finish** to create the model and exit the wizard.

Figure 22.52. Entity Data Model Wizard Screen 3

7. Visual Studio will generate the model and then display it.

Figure 22.53. Entity Data Model Diagram

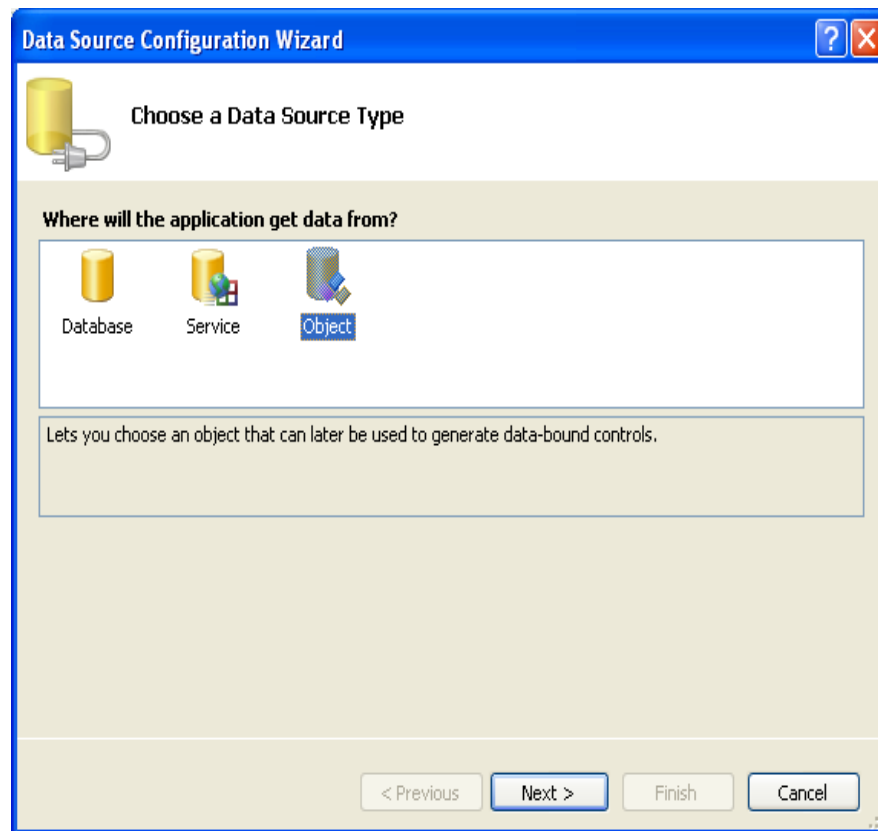

8. From the Visual Studio main menu select **Build, Build Solution**, to ensure that everything compiles correctly so far.

Adding a new Data Source

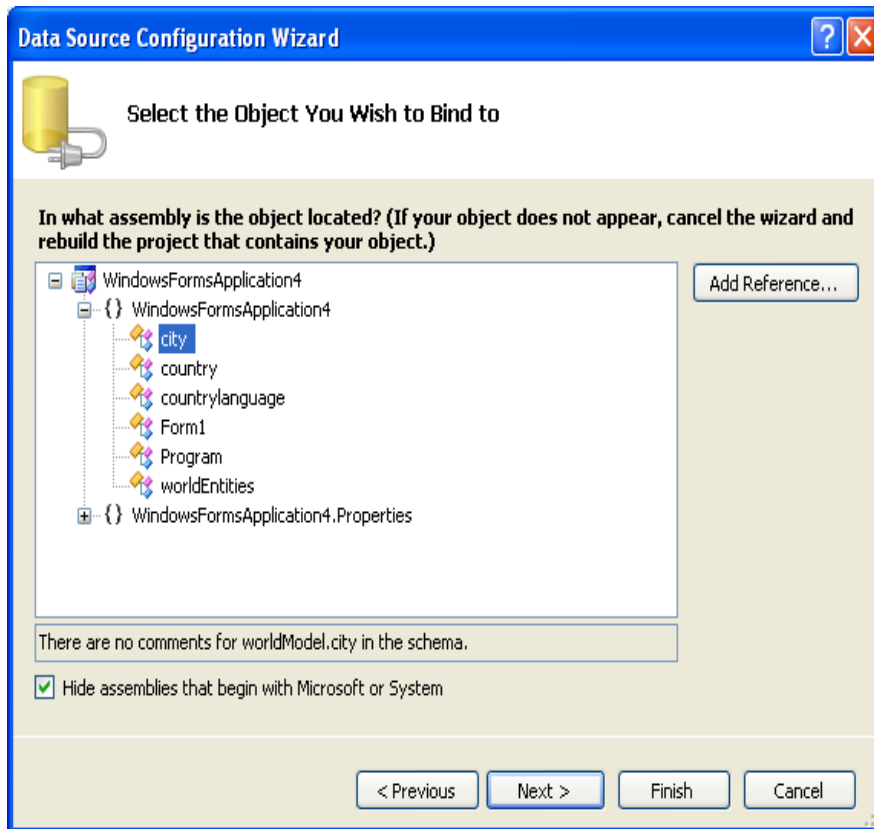

You will now add a new Data Source to your project and see how it can be used to read and write to the database.

1. From the Visual Studio main menu select **Data, Add New Data Source...**. You will be presented with the Data Source Configuration Wizard.

Figure 22.54. Entity Data Source Configuration Wizard Screen 1

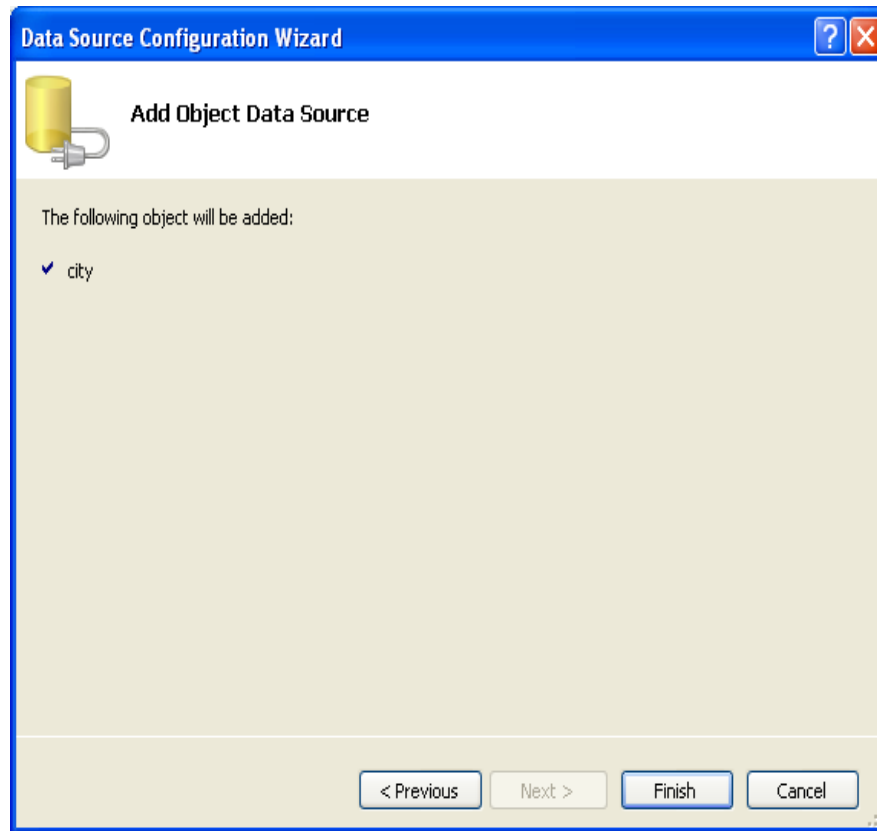

2. Select the **Object** icon. Click **Next**.
3. You will now select the Object to bind to. Expand the tree. In this tutorial, you will select the city table. Once the city table has been selected click **Next**.

Figure 22.55. Entity Data Source Configuration Wizard Screen 2

4. The wizard will confirm that the city object is to be added. Click **Finish**.

Figure 22.56. Entity Data Source Configuration Wizard Screen 3

5. The city object will be display in the Data Sources panel. If the Data Sources panel is not displayed, select Data, Show Data Sources from the Visual Studio main menu. The docked panel will then be displayed.

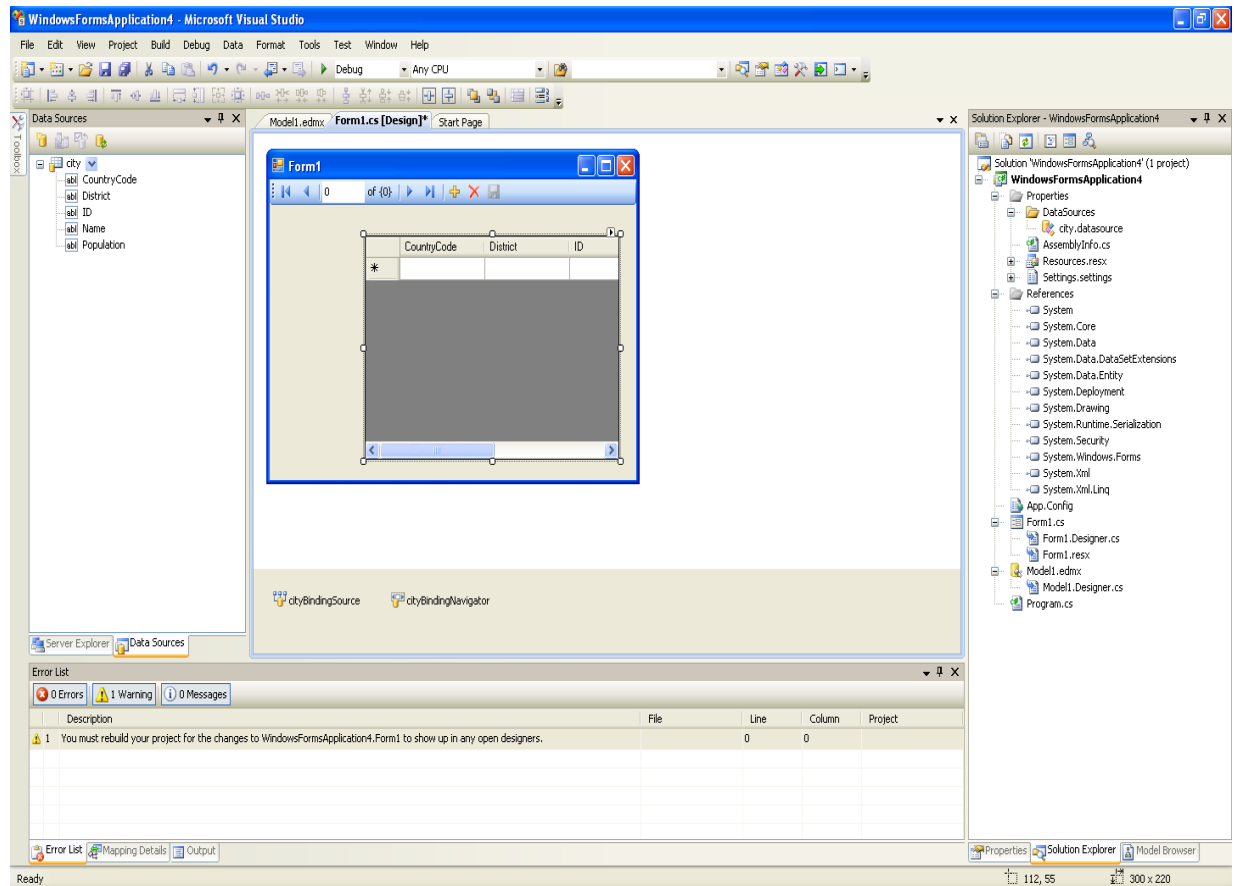

Figure 22.57. Data Sources

Using the Data Source in a Windows Form

You will now learn how to use the Data Source in a Windows Form.

1. In the Data Sources panel select the Data Source you just created and drag and drop it onto the Form Designer. By default the Data Source object will be added as a Data Grid View control. Note that the Data Grid View control is bound to the `cityBindingSource` and the Navigator control is bound to `cityBindingNavigator`.

Figure 22.58. Data Form Designer

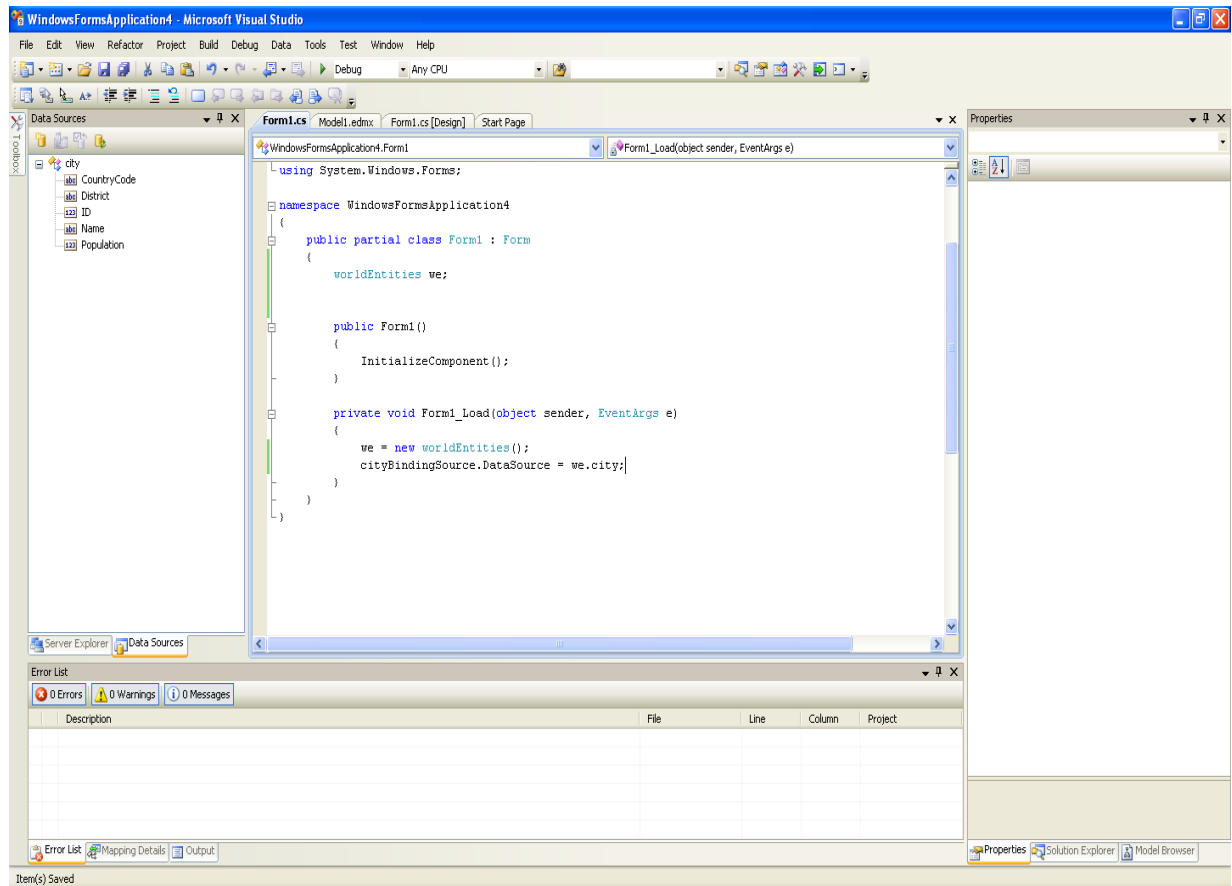

2. Save and rebuild the solution before continuing.

Adding Code to Populate the Data Grid View

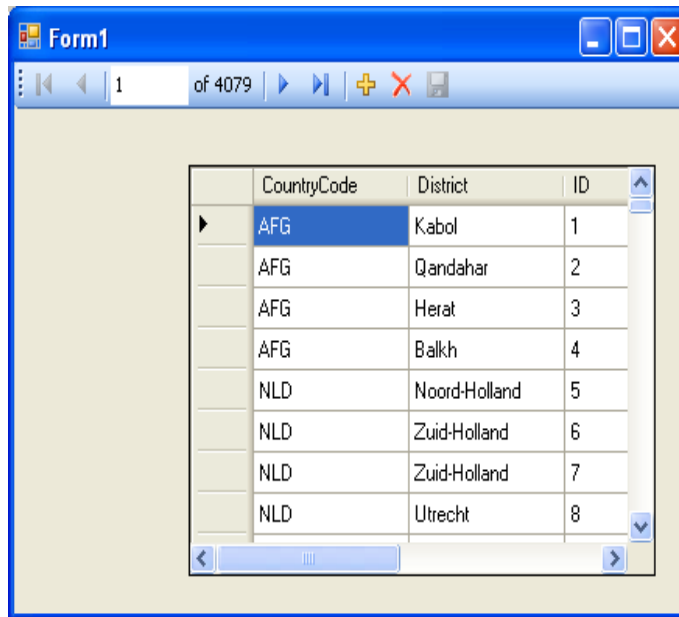

You are now ready to add code to ensure that the Data Grid View control will be populated with data from the City database table.

1. Double-click the form to access its code.
2. Add code to instantiate the Entity Data Model's EntityContainer object and retrieve data from the database to populate the control.

Figure 22.59. Adding Code to the Form

3. Save and rebuild the solution.
4. Run the solution. Ensure the grid is populated and you can navigate the database.

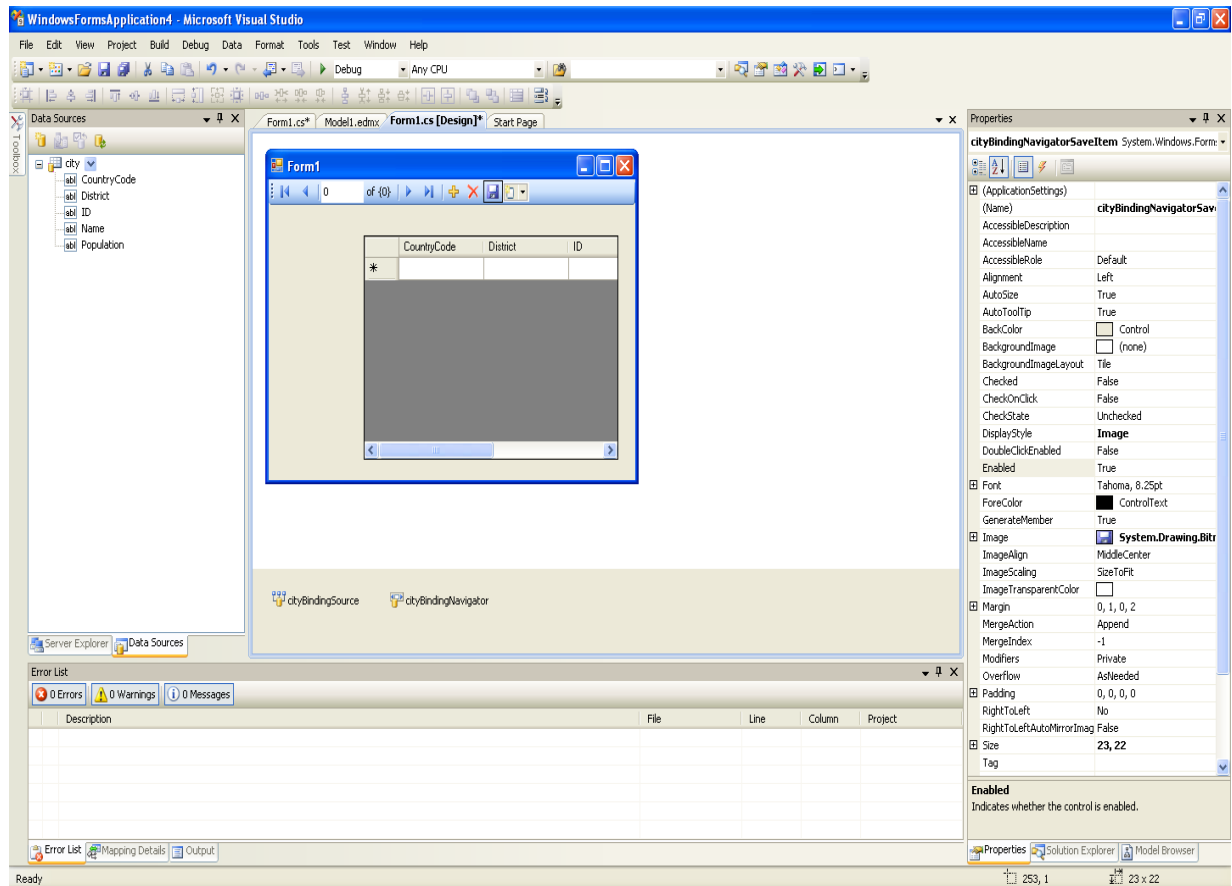

Figure 22.60. The Populated Grid Control**Adding Code to Save Changes to the Database**

You will now add code to enable you to save changes to the database.

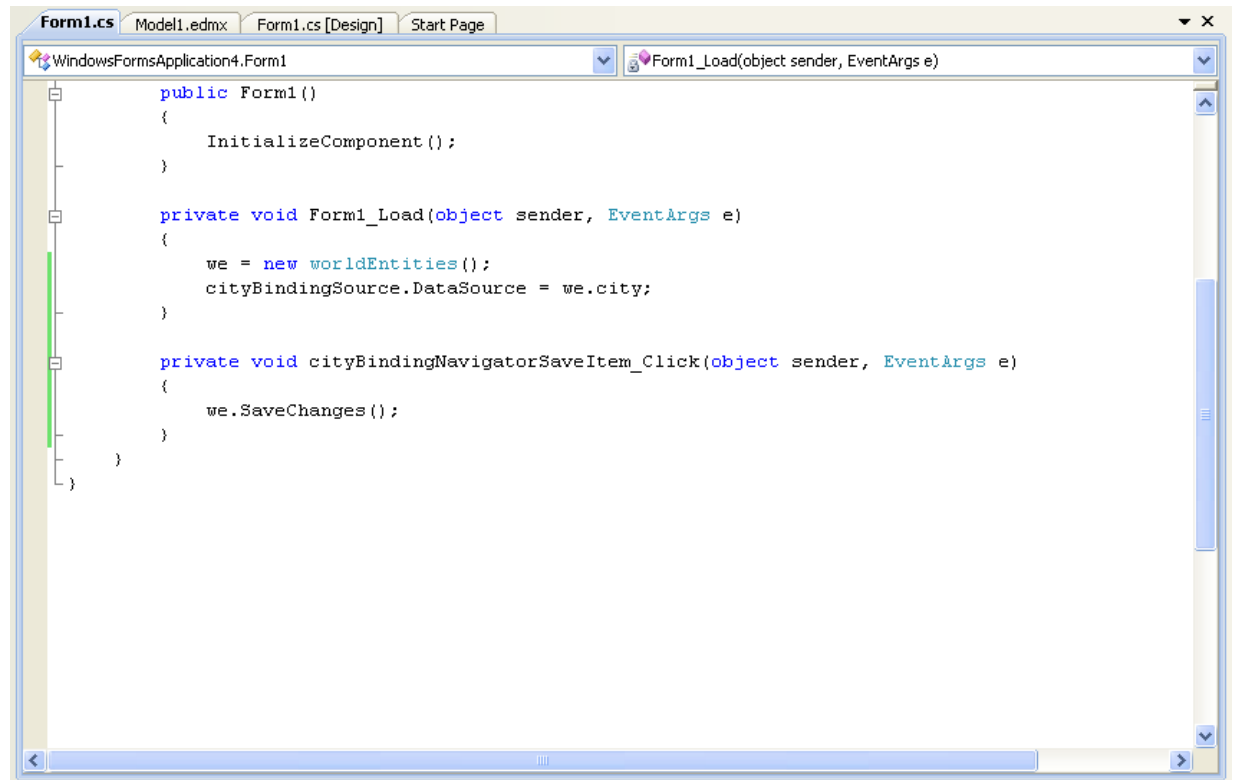

The Binding source component ensures that changes made in the Data Grid View control are also made to the Entity classes bound to it. However, that data needs to be saved back from the entities to the database itself. This can be achieved by the enabling of the Save button in the Navigator control, and the addition of some code.

1. In the Form Designer, click the Save icon in the Form toolbar and ensure that its Enabled property is set to True.

Figure 22.61. Save Button Enabled

2. Double-click the Save icon in the Form toolbar to display its code.
3. You now need to add code to ensure that data is saved to the database when the save button is clicked in the application.

Figure 22.62. Adding Save Code to the Form

4. Once the code has been added, save the solution and rebuild it. Run the application and verify that changes made in the grid are saved.

22.2.4.6. Tutorial: Databinding in ASP.NET using LINQ on Entities

In this tutorial you create an ASP.NET web page that binds LINQ queries to entities using the Entity Framework mapping.

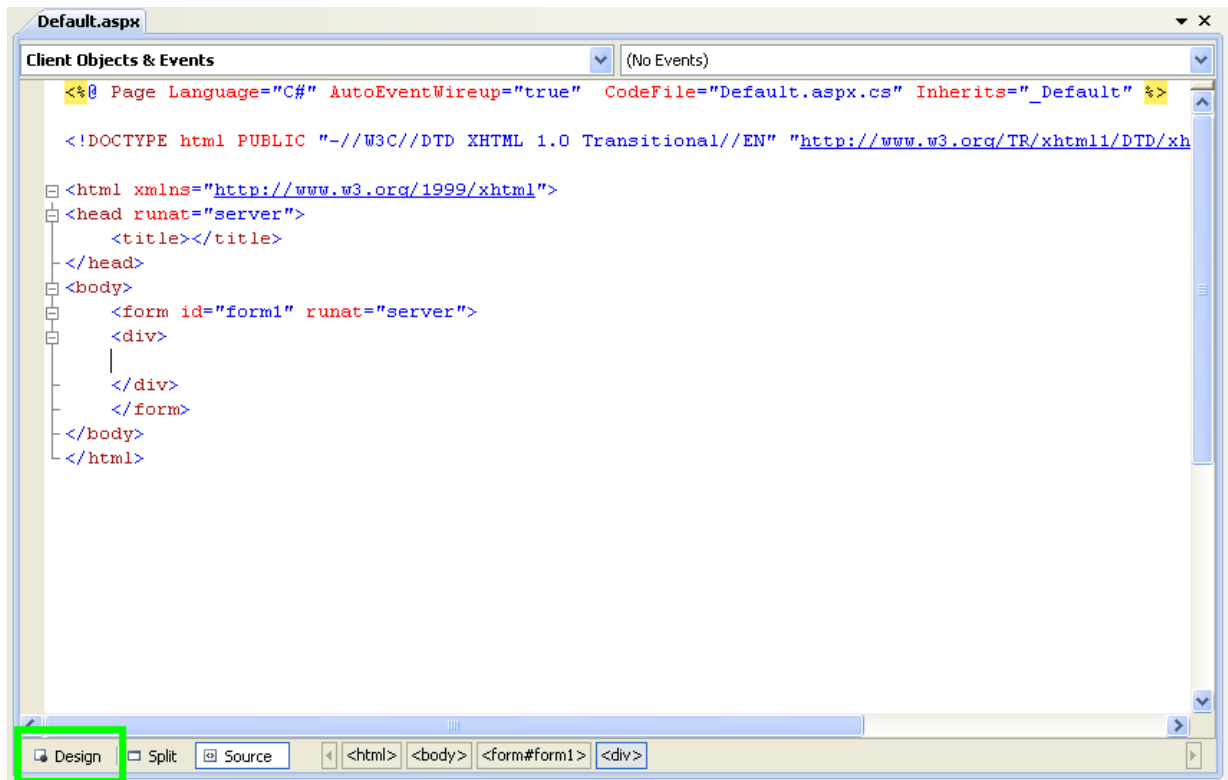

If you have not already done so, install the World example database prior to attempting this tutorial. See the tutorial [Section 22.2.4.5, "Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source"](#) for instructions on downloading and installing this database.

Creating an ASP.NET web site

In this part of the tutorial, you create an ASP.NET web site. The web site uses the World database. The main web page features a drop down list from which you can select a country. Data about that country's cities is then displayed in a grid view control.

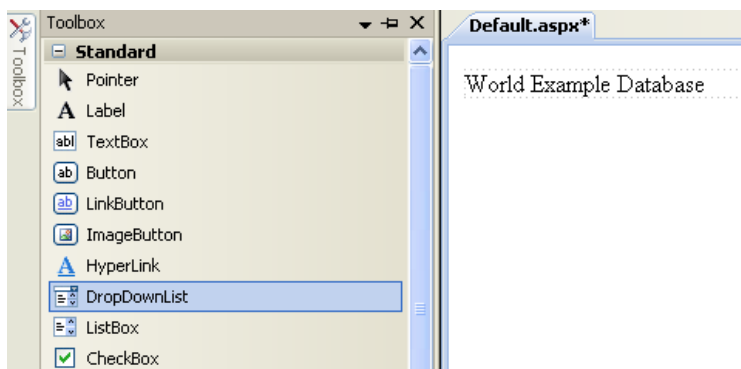

1. From the Visual Studio main menu select **File, New, Web Site...**
2. From the Visual Studio installed templates select **ASP.NET Web Site**. Click OK. You will be presented with the Source view of your web page by default.
3. Click the Design view tab situated underneath the Source view panel.

Figure 22.63. The Design Tab

4. In the Design view panel, enter some text to decorate the blank web page.
5. Click Toolbox. From the list of controls select **DropDownList**. Drag and drop the control to a location beneath the text on your web page.

Figure 22.64. Drop Down List

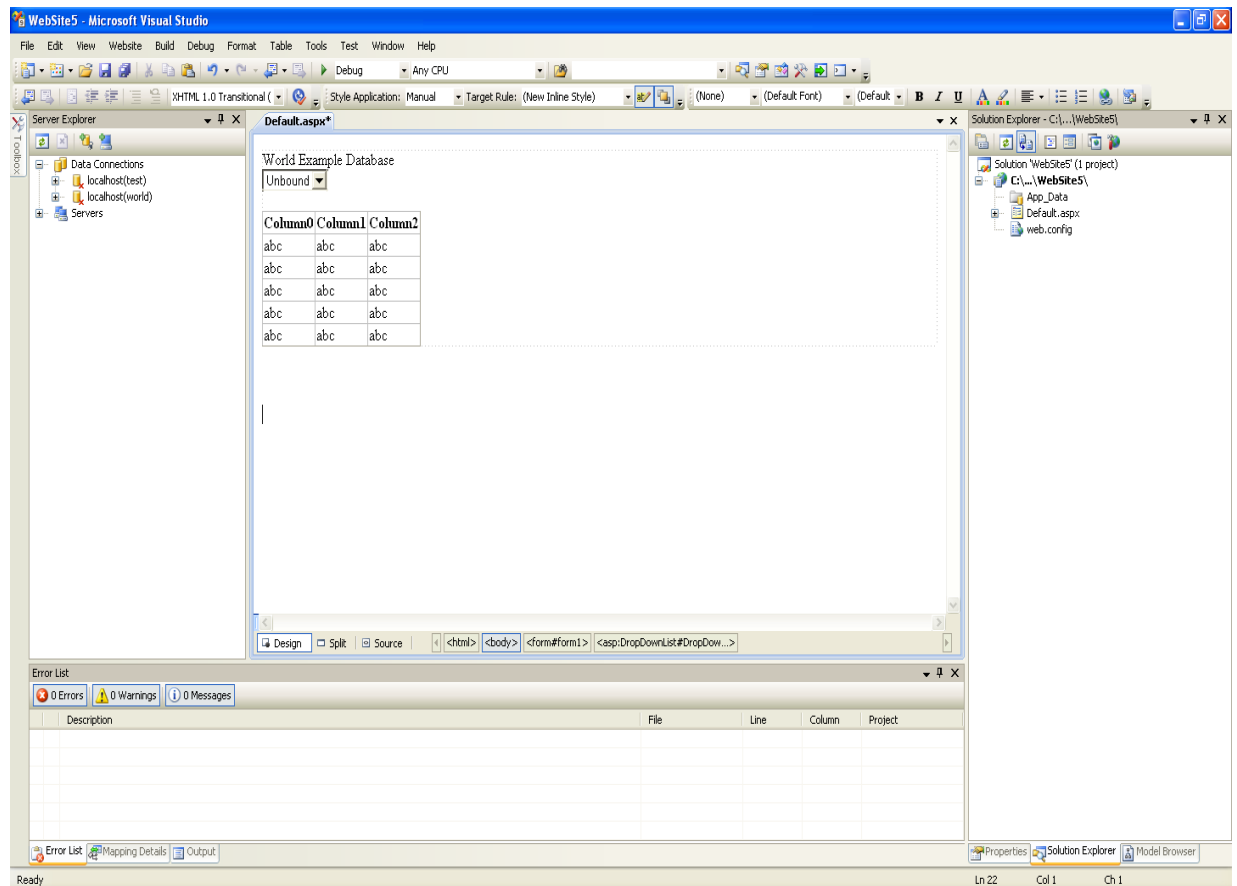

6. From the **DropDownList** control's context menu, ensure that the **Enable AutoPostBack** check box is enabled. This will ensure the control's event handler is called when an item is selected. The user's choice will in turn be used to populate the **GridView** control.

Figure 22.65. Enable AutoPostBack

7. From the Toolbox select the **GridView** control.

Figure 22.66. Grid View Control

Drag and drop the Grid View control to a location just below the Drop Down List you already placed.

Figure 22.67. Placed Grid View Control

8. At this point it is recommended that you save your solution, and build the solution to ensure that there are no errors.

9. If you run the solution you will see that the text and drop down list are displayed, but the list is empty. Also, the grid view does not appear at all. Adding this functionality is described in the following sections.

At this stage you have a web site that will build, but further functionality is required. The next step will be to use the Entity Framework to create a mapping from the World database into entities that you can control programmatically.

Creating an ADO.NET Entity Data Model

In this stage of the tutorial you will add an ADO.NET Entity Data Model to your project, using the World database at the storage level. The procedure for doing this is described in the tutorial [Section 22.2.4.5, "Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source"](#), and so will not be repeated here.

Populating a Drop Data List Box with using the results of a entity LINQ query

In this part of the tutorial you will write code to populate the DropDownList control. When the web page loads the data to populate the list will be achieved by using the results of a LINQ query on the model created previously.

1. In the Design view panel, double-click any blank area. This brings up the `Page_Load` method.
2. Modify the relevant section of code according to the following listing:

```
...
public partial class _Default : System.Web.UI.Page
{
    worldModel.worldEntities we;

    protected void Page_Load(object sender, EventArgs e)
    {
        we = new worldModel.worldEntities();

        if (!IsPostBack)
        {
            var countryQuery = from c in we.country
                               orderby c.Name
                               select new { c.Code, c.Name };
            DropDownList1.DataValueField = "Code";
            DropDownList1.DataTextField = "Name";
            DropDownList1.DataSource = countryQuery;
            DataBind();
        }
    }
}
...
```

Note that the list control only needs to be populated when the page first loads. The conditional code ensures that if the page is subsequently reloaded, the list control is not repopulated, which would cause the user selection to be lost.

3. Save the solution, build it and run it. You should see the list control has been populated. You can select an item, but as yet the grid view control does not appear.

At this point you have a working Drop Down List control, populated by a LINQ query on your entity data model.

Populating a Grid View control using an entity LINQ query

In the last part of this tutorial you will populate the Grid View Control using a LINQ query on your entity data model.

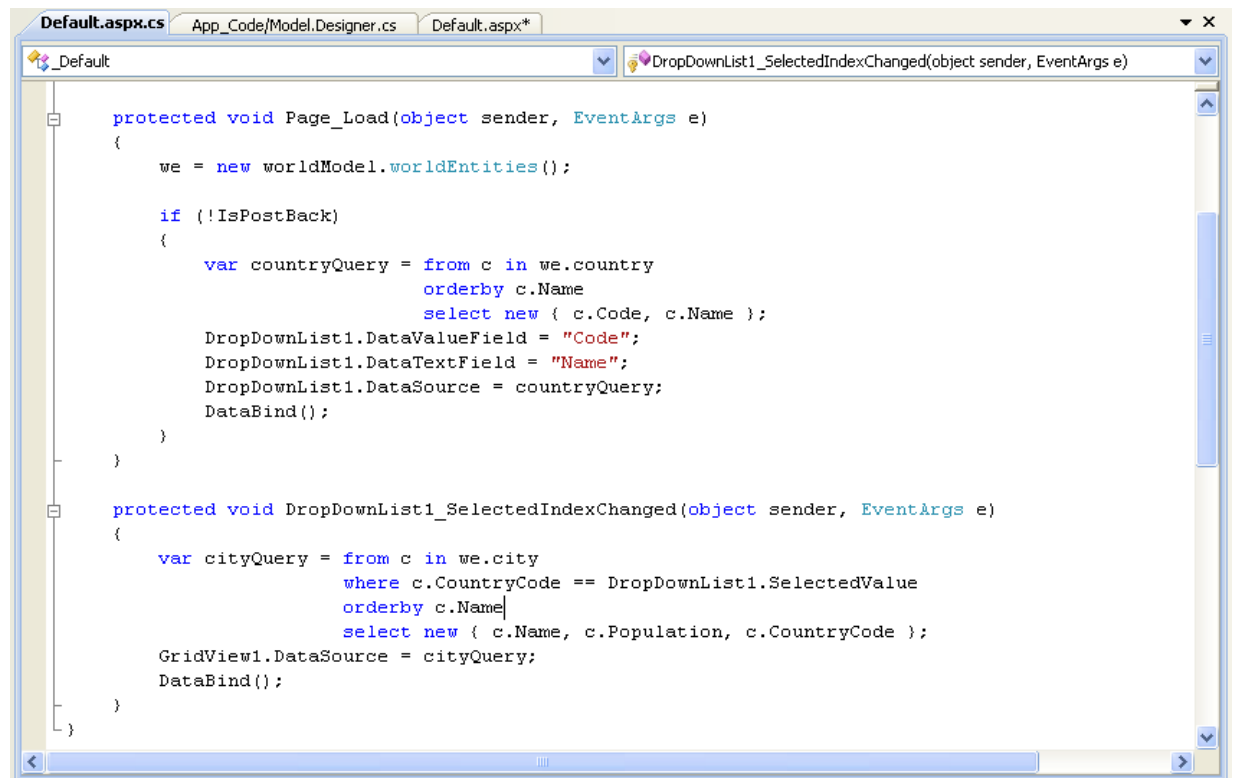

1. In the Design view, double-click the **DropDownList** control. This causes its `SelectedIndexChanged` code to be displayed. This method is called when a user selects an item in the list control and thus fires an `AutoPostBack` event.
2. Modify the relevant section of code accordingly to the following listing:

```
...
protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    var cityQuery = from c in we.city
                    where c.CountryCode == DropDownList1.SelectedValue
                    orderby c.Name
                    select new { c.Name, c.Population, c.CountryCode };
    GridView1.DataSource = cityQuery;
    DataBind();
}
...
```

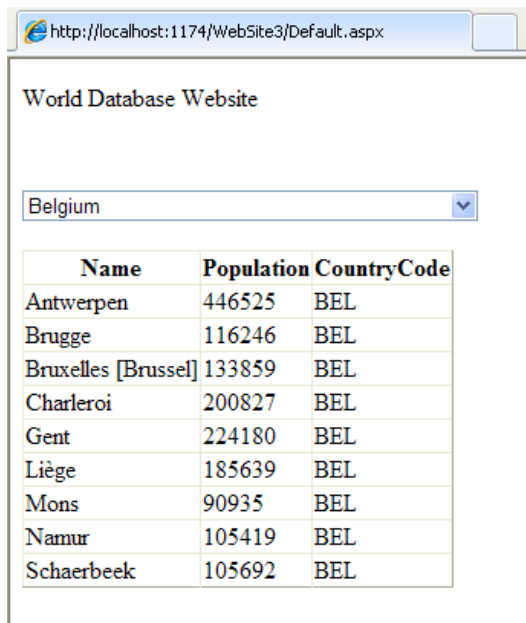

The grid view control is populated from the result of the LINQ query on the entity data model.

3. As a check compare your code to that shown in the following screenshot:

Figure 22.68. Source Code

4. Save, build and run the solution. As you select a country you will see its cities are displayed in the grid view control.

Figure 22.69. The Working Web Site

In this tutorial you have seen how to create an ASP.NET web site, you have also seen how you can access a MySQL database using LINQ queries on an entity data model.

22.2.4.7. Tutorial: Using SSL with MySQL Connector/Net

In this tutorial you will learn how you can use MySQL Connector/Net to connect to a MySQL server configured to use SSL. Support for SSL client certificates was added with MySQL Connector/Net 6.2.

MySQL Server uses the PEM format for certificates and private keys. This tutorial will use the test certificates from the server test suite by way of example. You can obtain the MySQL Server source code from [MySQL Downloads](#). The certificates can be found in the directory `./mysql-test/std_data`.

To carry out the steps in this tutorial, you must have Open SSL installed. This can be downloaded for Microsoft Windows at no charge from [Shining Light Productions](#).

Further details on the connection string options used in this tutorial can be found at [Section 22.2.6, "Connector/Net Connection String Options Reference"](#).

Configuring the MySQL Server to use SSL

1. In the MySQL Server configuration file, set the SSL parameters as follows:

```
ssl-ca=path/to/repo/mysql-test/std_data/cacert.pem
ssl-cert=path/to/repo/mysql-test/std_data/server-cert.pem
ssl-key=path/to/repo/mysql-test/std_data/server-key.pem
```

Adjust the directories according to the location in which you installed the MySQL source code.

2. In this step you create a test user and set the user to require SSL.

Using the MySQL Command Line Client, connect as root and create the user `sslclient`.

3. To set privileges and requirements, issue the following command:

```
GRANT ALL PRIVILEGES ON *.* TO sslclient@%' REQUIRE SSL;
```

Creating a certificate file to use with the .NET client

1. The .NET client does not use the PEM file format, as .NET does not support this format natively. You will be using test client certificates from the same server repository, for the purposes of this example. Convert these to PFX format first. This format is also known as PKCS#12. An article describing this procedure can be found at the [Citrix website](#). From the directory `server-repository-root/mysql-test/std_data`, issue the following command:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -certfile cacert.pem -out client.pfx
```

2. When asked for an export password, enter the password "pass". The file `client.pfx` will be generated. This file is used in the remainder of the tutorial.

Connecting to the server using a file-based certificate

1. You will use PFX file, `client.pfx` you created in the previous step to authenticate the client. The following example demonstrates how to connect using the `SSL Mode`, `CertificateFile` and `CertificatePassword` connection string options:

```
using (MySQLConnection connection = new MySQLConnection(
    "database=test;user=sslclient;" +
    "CertificateFile=H:\bzz\mysql-trunk\mysql-test\std_data\client.pfx" +
    "CertificatePassword=pass;" +
    "SSL Mode=Required "))
{
    connection.Open();
}
```

The path to the certificate file will need to be changed to reflect your individual installation.

Connecting to the server using a store-based certificate

1. The first step is to import the PFX file, `client.pfx`, into the Personal Store. Double-click the file in Windows explorer. This launches the Certificate Import Wizard.
2. Follow the steps dictated by the wizard, and when prompted for the password for the PFX file, enter "pass".
3. Click **Finish** to close the wizard and import the certificate into the personal store.

Examine certificates in the Personal Store

1. Start the Microsoft Management Console by entering `mmc.exe` at a command prompt.
2. Select **File**, **Add/Remove snap-in**. Click **Add**. Select **Certificates** from the list of available snap-ins in the dialog.
3. Click **Add** button in the dialog, and select the **My user account** radio button. This is used for personal certificates.
4. Click the **Finish** button.
5. Click **OK** to close the Add/Remove Snap-in dialog.
6. You will now have **Certificates – Current User** displayed in the left panel of the Microsoft Management Console. Expand the Certificates - Current User tree item and select **Personal, Certificates**. The right-hand panel will display a certificate issued to MySQL. This is the certificate that was previously imported. Double-click the certificate to display its details.

7. After you have imported the certificate to the Personal Store, you can use a more succinct connection string to connect to the database, as illustrated by the following code:

```
using (MySQLConnection connection = new MySQLConnection(
    "database=test;user=sslclient;" +
    "Certificate Store Location=CurrentUser;" +
    "SSL Mode=Required"))
{
    connection.Open();
}
```

Certificate Thumbprint Parameter

If you have a large number of certificates in your store, and many have the same Issuer, this can be a source of confusion and result in the wrong certificate being used. To alleviate this situation, there is an optional Certificate Thumbprint parameter that can additionally be specified as part of the connection string. As mentioned before, you can double-click a certificate in the Microsoft Management Console to display the certificate's details. When the Certificate dialog is displayed click the **Details** tab and scroll down to see the thumbprint. The thumbprint will typically be a number such as `#47 94 36 00 9a 40 f3 01 7a 14 5c f8 47 9e 76 94 d7 aa de f0`. This thumbprint can be used in the connection string, as the following code illustrates:

```
using (MySQLConnection connection = new MySQLConnection(
    "database=test;user=sslclient;" +
    "Certificate Store Location=CurrentUser;" +
    "Certificate Thumbprint=479436009a40f3017a145cf8479e7694d7aadef0;" +
    "SSL Mode=Required"))
{
    connection.Open();
}
```

Spaces in the thumbprint parameter are optional and the value is case-insensitive.

22.2.4.8. Tutorial: Using MySqlCommand

This tutorial teaches you how to use the `MySqlCommand` class. This class enables you to execute a series of statements. Depending on the circumstances, this can be more convenient than using the `MySQLCommand` approach.

Further details of the `MySqlCommand` class can be found in the reference documentation supplied with MySQL Connector/Net.

To run the example programs in this tutorial, set up a simple test database and table using the `mysql` Command Line Client or MySQL Workbench. Commands for the `mysql` Command Line Client are given here:

```
CREATE DATABASE TestDB;
USE TestDB;
CREATE TABLE TestTable (id INT NOT NULL PRIMARY KEY
    AUTO_INCREMENT, name VARCHAR(100));
```

The main method of the `MySqlCommand` class is the `Execute` method. This method causes the script (sequence of statements) assigned to the Query property of the `MySqlCommand` object to be executed. Note the Query property can be set through the `MySqlCommand` constructor or using the Query property. `Execute` returns the number of statements executed.

The `MySqlCommand` object will execute the specified script on the connection set using the Connection property. Again, this property can be set directly or through the `MySqlCommand` constructor. The following code snippets illustrate this:

```

string sql = "SELECT * FROM TestTable";
...
MySQLScript script = new MySQLScript(conn, sql);
...
MySQLScript script = new MySQLScript();
script.Query = sql;
script.Connection = conn;
...
script.Execute();

```

The MySQLScript class has several events associated with it. There are:

1. Error - generated if an error occurs.
2. ScriptCompleted - generated when the script successfully completes execution.
3. StatementExecuted - generated after each statement is executed.

It is possible to assign event handlers to each of these events. These user-provided routines are called back when the connected event occurs. The following code shows how the event handlers are set up.

```

script.Error += new MySQLScriptErrorHandler(script_Error);
script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
script.StatementExecuted += new MySQLStatementExecutedEventHandler(script_StatementExecuted);

```

In VisualStudio, you can save typing by using tab completion to fill out stub routines. Start by typing, for example, "script.Error +=". Then press **TAB**, and then press **TAB** again. The assignment is completed, and a stub event handler created. A complete working example is shown below:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace MySQLScriptTest
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "INSERT INTO TestTable(name) VALUES ('Superman');" +
                    "INSERT INTO TestTable(name) VALUES ('Batman');" +
                    "INSERT INTO TestTable(name) VALUES ('Wolverine');" +
                    "INSERT INTO TestTable(name) VALUES ('Storm');"

                MySQLScript script = new MySQLScript(conn, sql);

                script.Error += new MySQLScriptErrorHandler(script_Error);
                script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
                script.StatementExecuted += new MySQLStatementExecutedEventHandler(script_StatementExecuted);

                int count = script.Execute();
            }
            catch { }
        }
    }
}

```

```

        Console.WriteLine("Executed " + count + " statement(s).");
        Console.WriteLine("Delimiter: " + script.Delimiter);
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.ToString());
    }

    conn.Close();
    Console.WriteLine("Done.");
}

static void script_StatementExecuted(object sender, MySqlScriptEventArgs args)
{
    Console.WriteLine("script_StatementExecuted");
}

static void script_ScriptCompleted(object sender, EventArgs e)
{
    /// EventArgs e will be EventArgs.Empty for this method
    Console.WriteLine("script_ScriptCompleted!");
}

static void script_Error(Object sender, MySqlScriptErrorEventArgs args)
{
    Console.WriteLine("script_Error: " + args.Exception.ToString());
}
}
}

```

Note that in the `script_ScriptCompleted` event handler, the `EventArgs` parameter `e` will be `EventArgs.Empty`. In the case of the `ScriptCompleted` event there is no additional data to be obtained, which is why the event object is `EventArgs.Empty`.

22.2.4.8.1. Using Delimiters with MySqlScript

Depending on the nature of the script, you may need control of the delimiter used to separate the statements that will make up a script. The most common example of this is where you have a multi-statement stored routine as part of your script. In this case if the default delimiter of “;” is used you will get an error when you attempt to execute the script. For example, consider the following stored routine:

```

CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;
    SELECT COUNT(name) FROM TestTable;
END

```

This routine actually needs to be executed on the MySQL Server as a single statement. However, with the default delimiter of “;”, the `MySqlScript` class would interpret the above as two statements, the first being:

```

CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;

```

Executing this as a statement would generate an error. To solve this problem `MySqlScript` supports the ability to set a different delimiter. This is achieved through the `Delimiter` property. For example, you could set the delimiter to “??”, in which case the above stored routine would no longer generate an error when executed. Multiple statements can be delimited in the script, so for example, you could have a three statement script such as:

```

string sql = "DROP PROCEDURE IF EXISTS test_routine?? " +
            "CREATE PROCEDURE test_routine() " +

```

```
"BEGIN " +
"SELECT name FROM TestTable ORDER BY name;" +
"SELECT COUNT(name) FROM TestTable;" +
"END??" +
"CALL test_routine()";
```

You can change the delimiter back at any point by setting the Delimiter property. The following code shows a complete working example:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication8
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "DROP PROCEDURE IF EXISTS test_routine??" +
                    "CREATE PROCEDURE test_routine() " +
                    "BEGIN " +
                    "SELECT name FROM TestTable ORDER BY name;" +
                    "SELECT COUNT(name) FROM TestTable;" +
                    "END??" +
                    "CALL test_routine()";

                MySqlScript script = new MySqlScript(conn);

                script.Query = sql;
                script.Delimiter = "??";
                int count = script.Execute();
                Console.WriteLine("Executed " + count + " statement(s)");
                script.Delimiter = ";";
                Console.WriteLine("Delimiter: " + script.Delimiter);
                Console.WriteLine("Query: " + script.Query);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

22.2.4.9. Tutorial: Generating MySQL DDL from an Entity Framework Model

In this tutorial, you will learn how to create MySQL [DDL](#) from an Entity Framework model. Use Visual Studio 2010 and MySQL Connector/Net 6.3 to carry out this tutorial.

1. Create a new console application in Visual Studio 2010.

2. Using the **Solution Explorer**, add a reference to `MySQL.Data.Entity`.
3. From the **Solution Explorer** select **Add, New Item**. In the **Add New Item** dialog select **Online Templates**. Select **ADO.NET Entity Data Model** and click **Add**. The **Entity Data Model** dialog will be displayed.
4. In the **Entity Data Model** dialog select **Empty Model**. Click **Finish**. A blank model will be created.
5. Create a simple model. A single Entity will do for the purposes of this tutorial.
6. In the **Properties** panel select `ConceptualEntityModel` from the drop-down listbox.
7. In the **Properties** panel, locate the **DDL Generation Template** in the category **Database Script Generation**.
8. For the **DDL Generation** property select `SSDLToMySQL.tt(VS)` from the drop-down listbox.
9. Save the solution.
10. Right-click an empty space in the model design area. The context-sensitive menu will be displayed.
11. From the context-sensitive menu select **Generate Database from Model**. The **Generate Database Wizard** dialog will be displayed.
12. In the **Generate Database Wizard** dialog select an existing connection, or create a new connection to a server. Select an appropriate radio button to show or hide sensitive data. For the purposes of this tutorial you can select **Yes** (although you might skip this for commercial applications).
13. Click **Next**. MySQL compatible DDL code will be generated. Click **Finish** to exit the wizard.

You have seen how to create MySQL DDL code from an Entity Framework model.

22.2.5. Connector/Net Programming

Connector/Net comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/Net:

- `MySQLCommand`: Represents an SQL statement to execute against a MySQL database.
- `MySQLCommandBuilder`: Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- `MySQLConnection`: Represents an open connection to a MySQL Server database.
- `MySQLDataAdapter`: Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database.
- `MySQLDataReader`: Provides a means of reading a forward-only stream of rows from a MySQL database.
- `MySQLException`: The exception that is thrown when MySQL returns an error.
- `MySQLHelper`: Helper class that makes it easier to work with the provider.
- `MySQLTransaction`: Represents an SQL **transaction** to be made in a MySQL database.

In the following sections, you will learn about some common use cases for Connector/Net, including BLOB handling, date handling, and using Connector/Net with common tools such as Crystal Reports.

22.2.5.1. Connecting to MySQL Using Connector/Net

All interaction between a .NET application and the MySQL server is routed through a `MySqlConnection` object. Before your application can interact with the server, it must instantiate, configure, and open a `MySqlConnection` object.

Even when using the `MySqlHelper` class, a `MySqlConnection` object is created by the helper class.

This section describes how to connect to MySQL using the `MySqlConnection` object.

22.2.5.2. Creating a Connector/Net Connection String

The `MySqlConnection` object is configured using a connection string. A connection string contains several key/value pairs, separated by semicolons. In each key/value pair, the option name and its corresponding value are joined by an equal sign. For the list of option names to use in the connection string, see [Section 22.2.6, “Connector/Net Connection String Options Reference”](#).

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the `MySqlConnection` object is configured to connect to a MySQL server at `127.0.0.1`, with a user name of `root` and a password of `12345`. The default database for all statements will be the `test` database.

Note

Using the '@' symbol for parameters is now the preferred approach, although the old pattern of using '?' is still supported. To avoid conflicts when using the '@' symbol in combination with user variables, see the [Allow User Variables](#) connection string option in [Section 22.2.6, “Connector/Net Connection String Options Reference”](#). The [Old Syntax](#) connection string option has now been deprecated.

22.2.5.2.1. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySqlConnection` object, assign the connection string, and open the connection.

Connector/Net can also connect using the native Windows authentication plugin. See [Section 22.2.5.5, “Using the Windows Native Authentication Plugin”](#) for details.

You can further extend the authentication mechanism by writing your own authentication plugin. See [Section 22.2.5.6, “Writing a Custom Authentication Plugin”](#) for details.

Visual Basic Example

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
```

```
        & "uid=root;" _
        & "pwd=12345;" _
        & "database=test;"

Try
    conn.ConnectionString = myConnectionString
    conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
    MessageBox.Show(ex.Message)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection();
    conn.ConnectionString = myConnectionString;
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the [MySqlConnection](#) class:

Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    MessageBox.Show(ex.Message)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other Connector/Net classes to communicate with the MySQL server.

22.2.5.2.2. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of interest when handling errors:

- `Message`: A message that describes the current exception.
- `Number`: The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- `0`: Cannot connect to server.
- `1045`: Invalid user name and/or password.

The following code shows how to adapt the application's response based on the actual error:

Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    Select Case ex.Number
        Case 0
            MessageBox.Show("Cannot connect to server. Contact administrator")
        Case 1045
            MessageBox.Show("Invalid username/password, please try again")
    End Select
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    switch (ex.Number)
    {
        case 0:
            MessageBox.Show("Cannot connect to server. Contact administrator");
        case 1045:
```

```
        MessageBox.Show("Invalid username/password, please try again");  
    }  
}
```

Important

Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```
MySQLConnection myConnection = new MySQLConnection("server=127.0.0.1;uid=root;" +  
    "pwd=12345;database=test;Charset=latin1;");
```

22.2.5.2.3. Using GetSchema on a Connection

The `GetSchema()` method of the connection object can be used to retrieve schema information about the database currently connected to. The schema information is returned in the form of a `DataTable`. The schema information is organized into a number of collections. Different forms of the `GetSchema()` method can be used depending on the information required. There are three forms of the `GetSchema()` method:

- `GetSchema()` - This call will return a list of available collections.
- `GetSchema(String)` - This call returns information about the collection named in the string parameter. If the string "MetaDataCollections" is used then a list of all available collections is returned. This is the same as calling `GetSchema()` without any parameters.
- `GetSchema(String, String[])` - In this call the first string parameter represents the collection name, and the second parameter represents a string array of restriction values. Restriction values limit the amount of data that will be returned. Restriction values are explained in more detail in the [Microsoft .NET documentation](#).

22.2.5.2.3.1. Collections

The collections can be broadly grouped into two types: collections that are common to all data providers, and collections specific to a particular provider.

Common

The following collections are common to all data providers:

- MetaDataCollections
- DataSourceInformation
- DataTypes
- Restrictions
- ReservedWords

Provider-specific

The following are the collections currently provided by MySQL Connector/Net, in addition to the common collections above:

- Databases

- Tables
- Columns
- Users
- Foreign Keys
- IndexColumns
- Indexes
- Foreign Key Columns
- UDF
- Views
- ViewColumns
- Procedure Parameters
- Procedures
- Triggers

Example Code

A list of available collections can be obtained using the following code:

```
using System;
using System.Data;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication2
{
    class Program
    {
        private static void DisplayData(System.Data.DataTable table)
        {
            foreach (System.Data.DataRow row in table.Rows)
            {
                foreach (System.Data.DataColumn col in table.Columns)
                {
                    Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
                }
                Console.WriteLine("=====");
            }
        }

        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=world;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
            }
        }
    }
}
```

```

        DataTable table = conn.GetSchema("MetaDataCollections");
        //DataTable table = conn.GetSchema("UDF");
        DisplayData(table);

        conn.Close();
    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.ToString());
    }
    Console.WriteLine("Done.");
}
}
}

```

Further information on the `GetSchema()` method and schema collections can be found in the [Microsoft .NET documentation](#).

22.2.5.3. Using MySqlCommand

A `MySqlCommand` has the `CommandText` and `CommandType` properties associated with it. The `CommandText` will be handled differently depending on the setting of `CommandType`. `CommandType` can be one of:

1. Text - A SQL text command (default)
2. StoredProcedure - The name of a Stored Procedure
3. TableDirect - The name of a table (new in Connector/Net 6.2)

The default `CommandType`, `Text`, is used for executing queries and other SQL commands. Some example of this can be found in the following section [Section 22.2.4.1.2, "The MySqlCommand Object"](#).

If `CommandType` is set to `StoredProcedure`, set `CommandText` to the name of the Stored Procedure to access.

If `CommandType` is set to `TableDirect`, all rows and columns of the named table will be returned when you call one of the Execute methods. In effect, this command performs a `SELECT *` on the table specified. The `CommandText` property is set to the name of the table to query. This is illustrated by the following code snippet:

```

...
MySqlCommand cmd = new MySqlCommand();
cmd.CommandText = "mytable";
cmd.Connection = someConnection;
cmd.CommandType = CommandType.TableDirect;
MySqlDataReader reader = cmd.ExecuteReader();
while (reader.Read())
{
    Console.WriteLine(reader[0], reader[1]...);
}
...

```

Examples of using the `CommandType` of `StoredProcedure` can be found in the section [Section 22.2.5.9, "Accessing Stored Procedures with Connector/Net"](#).

Commands can have a timeout associated with them. This is useful as you may not want a situation where a command takes up an excessive amount of time. A timeout can be set using the `CommandTimeout` property. The following code snippet sets a timeout of one minute:

```

MySqlCommand cmd = new MySqlCommand();

```

```
cmd.CommandTimeout = 60;
```

The default value is 30 seconds. Avoid a value of 0, which indicates an indefinite wait. To change the default command timeout, use the connection string option [Default Command Timeout](#).

Prior to MySQL Connector/Net 6.2, [MySqlCommand.CommandTimeout](#) included user processing time, that is processing time not related to direct use of the connector. Timeout was implemented through a .NET Timer, that triggered after [CommandTimeout](#) seconds. This timer consumed a thread.

MySQL Connector/Net 6.2 introduced timeouts that are aligned with how Microsoft handles [SqlCommand.CommandTimeout](#). This property is the cumulative timeout for all network reads and writes during command execution or processing of the results. A timeout can still occur in the [MySqlReader.Read](#) method after the first row is returned, and does not include user processing time, only IO operations. The 6.2 implementation uses the underlying stream timeout facility, so is more efficient in that it does not require the additional timer thread as was the case with the previous implementation.

Further details on this can be found in the relevant [Microsoft documentation](#).

22.2.5.4. Using Connector/Net with Connection Pooling

The Connector/Net supports connection pooling for better performance and scalability with database-intensive applications. This is enabled by default. You can turn it off or adjust its performance characteristics using the connection string options [Pooling](#), [Connection Reset](#), [Connection Lifetime](#), [Cache Server Properties](#), [Max Pool Size](#) and [Min Pool Size](#). See [Section 22.2.5.2, "Creating a Connector/Net Connection String"](#) for further information.

Connection pooling works by keeping the native connection to the server live when the client disposes of a [MySqlConnection](#). Subsequently, if a new [MySqlConnection](#) object is opened, it will be created from the connection pool, rather than creating a new native connection. This improves performance.

Guidelines

To work as designed, it is best to let the connection pooling system manage all connections. Do not create a globally accessible instance of [MySqlConnection](#) and then manually open and close it. This interferes with the way the pooling works and can lead to unpredictable results or even exceptions.

One approach that simplifies things is to avoid manually creating a [MySqlConnection](#) object. Instead use the overloaded methods that take a connection string as an argument. Using this approach, Connector/Net will automatically create, open, close and destroy connections, using the connection pooling system for best performance.

Typed Datasets and the [MembershipProvider](#) and [RoleProvider](#) classes use this approach. Most classes that have methods that take a [MySqlConnection](#) as an argument, also have methods that take a connection string as an argument. This includes [MySqlDataAdapter](#).

Instead of manually creating [MySqlCommand](#) objects, you can use the static methods of the [MySqlHelper](#) class. These take a connection string as an argument, and they fully support connection pooling.

Resource Usage

Starting with MySQL Connector/Net 6.2, there is a background job that runs every three minutes and removes connections from pool that have been idle (unused) for more than three minutes. The pool cleanup frees resources on both client and server side. This is because on the client side every connection uses a socket, and on the server side every connection uses a socket and a thread.

Prior to this change, connections were never removed from the pool, and the pool always contained the peak number of open connections. For example, a web application that peaked at 1000 concurrent database connections would consume 1000 threads and 1000 open sockets at the server, without ever freeing up those resources from the connection pool. Note, connections, no matter how old, will not be closed if the number of connections in the pool is less than or equal to the value set by the `Min Pool Size` connection string parameter.

22.2.5.5. Using the Windows Native Authentication Plugin

Connector/Net applications can authenticate to a MySQL server using the Windows Native Authentication Plugin as of Connector/Net 6.4.4 and MySQL 5.5.16. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For background and usage information about the authentication plugin, see, [Section 6.3.6.3, “The Windows Native Authentication Plugin”](#).

The interface matches the `MySql.Data.MySqlClient` object. To enable, pass in `Integrated Security` to the connection string with a value of `yes` or `sspi`.

Passing in a user ID is optional. When Windows authentication is set up, a MySQL user is created and configured to be used by Windows authentication. By default, this user ID is named `auth_windows`, but can be defined using a different name. If the default name is used, then passing the user ID to the connection string from Connector/Net is optional, because it will use the `auth_windows` user. Otherwise, the name must be passed to the `connection string` using the standard user ID element.

22.2.5.6. Writing a Custom Authentication Plugin

Advanced users with special security requirements can create their own authentication plugins for Connector/Net applications. You can extend the handshake protocol, adding custom logic. This capability requires Connector/Net 6.6.3 or higher, and MySQL 5.5.16 or higher. For background and usage information about MySQL authentication plugins, see, [Section 23.2.3.7, “Authentication Plugins”](#) and [Section 23.2.4.9, “Writing Authentication Plugins”](#).

To write a custom authentication plugin, you will need a reference to the assembly `MySql.Data.dll`. The classes relevant for writing authentication plugins are available at the namespace `MySql.Data.MySqlClient.Authentication`.

How the Custom Authentication Plugin Works

At some point during handshake, the internal method

```
void Authenticate(bool reset)
```

of `MySqlAuthenticationPlugin` is called. This method in turns calls several overridable methods of the current plugin.

Creating the Authentication Plugin Class

You put the authentication plugin logic inside a new class derived from `MySql.Data.MySqlClient.Authentication.MySqlAuthenticationPlugin`. The following methods are available to be overridden:

```
protected virtual void CheckConstraints()  
protected virtual void AuthenticationFailed(Exception ex)  
protected virtual void AuthenticationSuccessful()  
protected virtual byte[] MoreData(byte[] data)  
protected virtual void AuthenticationChange()
```

```
public abstract string PluginName { get; }
public virtual string GetUsername()
public virtual object GetPassword()
protected byte[] AuthData;
```

The following is a brief explanation of each one:

```
/// <summary>
/// This method must check authentication method specific constraints in the
/// environment and throw an Exception
/// if the conditions are not met. The default implementation does nothing.
/// </summary>
protected virtual void CheckConstraints()

/// <summary>
/// This method, called when the authentication failed, provides a chance to
/// plugins to manage the error
/// the way they consider decide (either showing a message, logging it, etc.).
/// The default implementation wraps the original exception in a MySqlConnection
/// with an standard message and rethrows it.
/// </summary>
/// <param name="ex">The exception with extra information on the error.</param>
protected virtual void AuthenticationFailed(Exception ex)

/// <summary>
/// This method is invoked when the authentication phase was successful accepted
/// by the server.
/// Derived classes must override this if they want to be notified of such
/// condition.
/// </summary>
/// <remarks>The default implementation does nothing.</remarks>
protected virtual void AuthenticationSuccessful()

/// <summary>
/// This method provides a chance for the plugin to send more data when the
/// server requests so during the
/// authentication phase. This method will be called at least once, and more
/// than one depending upon whether the
/// server response packets have the 0x01 prefix.
/// </summary>
/// <param name="data">The response data from the server, during the
/// authentication phase the first time is called is null, in
/// subsequent calls contains the server response.</param>
/// <returns>The data generated by the plugin for server consumption.</returns>
/// <remarks>The default implementation always returns null.</remarks>
protected virtual byte[] MoreData(byte[] data)

/// <summary>
/// The plugin name.
/// </summary>
public abstract string PluginName { get; }

/// <summary>
/// Gets the user name to send to the server in the authentication phase.
/// </summary>
/// <returns>An string with the user name</returns>
/// <remarks>Default implementation returns the UserId passed from the
/// connection string.</remarks>
public virtual string GetUsername()

/// <summary>
/// Gets the password to send to the server in the authentication phase. This
/// can can be an string or a
/// </summary>
/// <returns>An object, can be byte[], string or null, with the password.
</returns>
```

```
/// <remarks>Default implementation returns null.</remarks>
public virtual object GetPassword()

/// <summary>
/// The authentication data passed when creating the plugin.
/// For example in mysql_native_password this is the seed to encrypt the
password.
/// </summary>
protected byte[] AuthData;
```

Sample Authentication Plugin

Here is an example showing how to create the authentication plugin, then enable it by means of a configuration file. Follow these steps:

1. Create a console app, adding a reference to `MySQL.Data.dll`.
2. Design the main program as follows:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using MySql.Data.MySqlClient;

namespace AuthPluginTest
{
    class Program
    {
        static void Main(string[] args)
        {
            // Customize the connection string as necessary.
            MySqlConnection con = new MySqlConnection("server=localhost;
database=test; user id=myuser; password=mypass");
            con.Open();
            con.Close();
        }
    }
}
```

3. Create your plugin class. In this example, we add an “alternative” implementation of the Native password plugin by just using the same code from the original plugin. We name our class `MySQLNativePasswordPlugin2`:

```
using System.IO;
using System;
using System.Text;
using System.Security.Cryptography;
using MySql.Data.MySqlClient.Authentication;
using System.Diagnostics;

namespace AuthPluginTest
{
    public class MySQLNativePasswordPlugin2 : MySQLAuthenticationPlugin
    {
        public override string PluginName
        {
            get { return "mysql_native_password"; }
        }

        public override object GetPassword()
        {
            Debug.WriteLine("Calling MySQLNativePasswordPlugin2.GetPassword");
        }
    }
}
```

```

    return Get411Password(Settings.Password, AuthData);
}

/// <summary>
/// Returns a byte array containing the proper encryption of the
/// given password/seed according to the new 4.1.1 authentication scheme.
/// </summary>
/// <param name="password"></param>
/// <param name="seed"></param>
/// <returns></returns>
private byte[] Get411Password(string password, byte[] seedBytes)
{
    // if we have no password, then we just return 1 zero byte
    if (password.Length == 0) return new byte[1];

    SHA1 sha = new SHA1CryptoServiceProvider();

    byte[] firstHash = sha.ComputeHash(Encoding.Default.GetBytes(password));
    byte[] secondHash = sha.ComputeHash(firstHash);

    byte[] input = new byte[seedBytes.Length + secondHash.Length];
    Array.Copy(seedBytes, 0, input, 0, seedBytes.Length);
    Array.Copy(secondHash, 0, input, seedBytes.Length, secondHash.Length);
    byte[] thirdHash = sha.ComputeHash(input);

    byte[] finalHash = new byte[thirdHash.Length + 1];
    finalHash[0] = 0x14;
    Array.Copy(thirdHash, 0, finalHash, 1, thirdHash.Length);

    for (int i = 1; i < finalHash.Length; i++)
        finalHash[i] = (byte)(finalHash[i] ^ firstHash[i - 1]);
    return finalHash;
}
}
}

```

4. Notice that the plugin implementation just overrides `GetPassword`, and provides an implementation to encrypt the password using the 4.1 protocol. We also put the following line in the `GetPassword` body:

```
Debug.WriteLine("Calling MySqlNativePasswordPlugin2.GetPassword");
```

to provide confirmation that the plugin was effectively used. (You could also put a breakpoint on that method.)

5. Enable the new plugin in the configuration file:

```

<?xml version="1.0"?>
<configuration>
  <configSections>
    <section name="MySQL" type="MySql.Data.MySqlClient.MySqlConfiguration,
MySql.Data"/>
  </configSections>
  <MySQL>
    <AuthenticationPlugins>
      <add name="mysql_native_password"
type="AuthPluginTest.MySqlNativePasswordPlugin2, AuthPluginTest"></add>
    </AuthenticationPlugins>
  </MySQL>
</startup><supportedRuntime version="v4.0" sku=".NETFramework,Version=v4.0"/>
</configuration>

```

6. Run the application. In Visual Studio, you will see the message `Calling MySqlNativePasswordPlugin2.GetPassword` in the debug window.
7. Continue enhancing the authentication logic, overriding more methods if you required.

22.2.5.7. Using Connector/Net with Table Caching

This feature exists with Connector/Net versions 6.4 and above.

Table caching is a feature that can be used to cache slow-changing datasets on the client side. This is useful for applications that are designed to use readers, but still want to minimize trips to the server for slow-changing tables.

This feature is transparent to the application, and is disabled by default.

Configuration

- To enable table caching, add `'table cache = true'` to the connection string.
- Optionally, specify the `'Default Table Cache Age'` connection string option, which represents the number of seconds a table is cached before the cached data is discarded. The default value is `60`.
- You can turn caching on and off and set caching options at runtime, on a per-command basis.

22.2.5.8. Using the Connector/Net with Prepared Statements

As of MySQL 4.1, it is possible to use prepared statements with Connector/Net. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

22.2.5.8.1. Preparing Statements in Connector/Net

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySQLCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
    conn.Open()
    cmd.Connection = conn
```

```

cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)"
cmd.Prepare()

cmd.Parameters.AddWithValue("@number", 1)
cmd.Parameters.AddWithValue("@text", "One")

For i = 1 To 1000
    cmd.Parameters("@number").Value = i
    cmd.Parameters("@text").Value = "A string value"

    cmd.ExecuteNonQuery()
Next
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

C# Example

```

MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)";
    cmd.Prepare();

    cmd.Parameters.AddWithValue("@number", 1);
    cmd.Parameters.AddWithValue("@text", "One");

    for (int i=1; i <= 1000; i++)
    {
        cmd.Parameters["@number"].Value = i;
        cmd.Parameters["@text"].Value = "A string value";

        cmd.ExecuteNonQuery();
    }
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

22.2.5.9. Accessing Stored Procedures with Connector/Net

MySQL server version 5 and up supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that is stored in the server. Clients make a single call to the stored procedure, passing parameters that can influence the procedure logic and query conditions, rather than issuing individual hardcoded SQL statements.

Stored procedures can be particularly useful in situations such as the following:

- Stored procedures can act as an API or abstraction layer, allowing multiple client applications to perform the same database operations. The applications can be written in different languages and run on different platforms. The applications do not need to hardcode table and column names, complicated

queries, and so on. When you extend and optimize the queries in a stored procedure, all the applications that call the procedure automatically receive the benefits.

- When security is paramount, stored procedures keep applications from directly manipulating tables, or even knowing details such as table and column names. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Connector/Net supports the calling of stored procedures through the `MySqlCommand` object. Data can be passed in and out of a MySQL stored procedure through use of the `MySqlCommand.Parameters` collection.

Note

When you call a stored procedure, the command object makes an additional `SELECT` call to determine the parameters of the stored procedure. You must ensure that the user calling the procedure has the `SELECT [697]` privilege on the `mysql.proc` table to enable them to verify the parameters. Failure to do this will result in an error when calling the procedure.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to <http://dev.mysql.com/doc/mysql/en/stored-routines.html>.

A sample application demonstrating how to use stored procedures with Connector/Net can be found in the `Samples` directory of your Connector/Net installation.

22.2.5.9.1. Using Stored Routines from Connector/Net

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using MySQL Workbench. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySqlCommand` object.

Unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in Connector/Net.

To call a stored procedure using Connector/Net, you create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. You then set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, you create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the data type that is expected to be returned. All parameters need the parameter direction defined.

After defining the parameters, you call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method.

Once the stored procedure is called, the values of the output parameters can be retrieved by using the `.Value` property of the `MySqlConnection.Parameters` collection.

Note

When a stored procedure is called using `MySqlCommand.ExecuteReader`, and the stored procedure has output parameters, the output parameters are only set after the `MySqlDataReader` returned by `ExecuteReader` is closed.

The following C# example code demonstrates the use of stored procedures. It assumes the database 'employees' has already been created:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace UsingStoredRoutines
{
    class Program
    {
        static void Main(string[] args)
        {
            MySqlConnection conn = new MySqlConnection();
            conn.ConnectionString = "server=localhost;user=root;database=employees;port=3306;password=****";
            MySqlCommand cmd = new MySqlCommand();

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
                cmd.Connection = conn;
                cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp";
                cmd.ExecuteNonQuery();
                cmd.CommandText = "DROP TABLE IF EXISTS emp";
                cmd.ExecuteNonQuery();
                cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY
                cmd.ExecuteNonQuery();

                cmd.CommandText = "CREATE PROCEDURE add_emp(" +
                    "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno
                    "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
                    "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

                cmd.ExecuteNonQuery();
            }
            catch (MySqlException ex)
            {
                Console.WriteLine("Error " + ex.Number + " has occurred: " + ex.Message);
            }
            conn.Close();
            Console.WriteLine("Connection closed.");
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
                cmd.Connection = conn;

                cmd.CommandText = "add_emp";
                cmd.CommandType = CommandType.StoredProcedure;

                cmd.Parameters.AddWithValue("@lname", "Jones");
                cmd.Parameters["@lname"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@fname", "Tom");
                cmd.Parameters["@fname"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@bday", "1940-06-07");
                cmd.Parameters["@bday"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32);
                cmd.Parameters["@empno"].Direction = ParameterDirection.Output;
```

```

        cmd.ExecuteNonQuery();

        Console.WriteLine("Employee number: "+cmd.Parameters["@empno"].Value);
        Console.WriteLine("Birthday: " + cmd.Parameters["@bday"].Value);
    }
    catch (MySql.Data.MySqlClient.MySqlException ex)
    {
        Console.WriteLine("Error " + ex.Number + " has occurred: " + ex.Message);
    }
    conn.Close();
    Console.WriteLine("Done.");
}
}
}

```

The following code shows the same application in Visual Basic:

```

Imports System
Imports System.Collections.Generic
Imports System.Linq
Imports System.Text

Imports System.Data
Imports MySql.Data
Imports MySql.Data.MySqlClient

Module Module1

    Sub Main()
        Dim conn As New MySqlConnection()
        conn.ConnectionString = "server=localhost;user=root;database=world;port=3306;password=*****;"
        Dim cmd As New MySqlCommand()

        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn
            cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "DROP TABLE IF EXISTS emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY, first"
            cmd.ExecuteNonQuery()

            cmd.CommandText = "CREATE PROCEDURE add_emp(" & "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bd"

            cmd.ExecuteNonQuery()
        Catch ex As MySqlException
            Console.WriteLine("Error " & ex.Number & " has occurred: ") + ex.Message)
        End Try
        conn.Close()
        Console.WriteLine("Connection closed.")
        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn

            cmd.CommandText = "add_emp"
            cmd.CommandType = CommandType.StoredProcedure

            cmd.Parameters.AddWithValue("@lname", "Jones")
            cmd.Parameters("@lname").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@fname", "Tom")
            cmd.Parameters("@fname").Direction = ParameterDirection.Input

```

```

cmd.Parameters.AddWithValue("@bday", "1940-06-07")
cmd.Parameters("@bday").Direction = ParameterDirection.Input

cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32)
cmd.Parameters("@empno").Direction = ParameterDirection.Output

cmd.ExecuteNonQuery()

Console.WriteLine("Employee number: " & cmd.Parameters("@empno").Value)
Console.WriteLine("Birthday: " & cmd.Parameters("@bday").Value)
Catch ex As MySql.Data.MySqlClient.MySqlException
    Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
End Try
conn.Close()
Console.WriteLine("Done.")

End Sub

End Module

```

22.2.5.10. Handling BLOB Data With Connector/Net

One common use for MySQL is the storage of binary data in **BLOB** columns. MySQL supports four different BLOB data types: **TINYBLOB**, **BLOB**, **MEDIUMBLOB**, and **LOB**, all described in [Section 11.4.3, “The BLOB and TEXT Types”](#) and [Section 11.6, “Data Type Storage Requirements”](#).

Data stored in a **BLOB** column can be accessed using Connector/Net and manipulated using client-side code. There are no special requirements for using Connector/Net with **BLOB** data.

Simple code examples will be presented within this section, and a full sample application can be found in the [Samples](#) directory of the Connector/Net installation.

22.2.5.10.1. Preparing the MySQL Server

The first step in using MySQL with **BLOB** data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an **AUTO_INCREMENT** column of appropriate size (**UNSIGNED SMALLINT**) to serve as a primary key to identify the file, a **VARCHAR** column that stores the file name, an **UNSIGNED MEDIUMINT** column that stores the size of the file, and a **MEDIUMBLOB** column that stores the file itself. For this example, I will use the following table definition:

```

CREATE TABLE file(
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
file_name VARCHAR(64) NOT NULL,
file_size MEDIUMINT UNSIGNED NOT NULL,
file MEDIUMBLOB NOT NULL);

```

After creating a table, you might need to modify the `max_allowed_packet` system variable. This variable determines how large of a packet (that is, a single row) can be sent to the MySQL server. By default, the server only accepts a maximum size of 1MB from the client application. If you intend to exceed 1MB in your file transfers, increase this number.

The `max_allowed_packet` option can be modified using the MySQL Workbench **Server Administration** screen. Adjust the Maximum permitted option in the **Data / Memory size** section of the Networking tab to an appropriate setting. After adjusting the value, click the **Apply** button and restart the server using the **Startup / Shutdown** screen of MySQL Workbench. You can also adjust this value directly in the `my.cnf` file (add a line that reads `max_allowed_packet=xxM`), or use the `SET max_allowed_packet=xxM;` syntax from within MySQL.

Try to be conservative when setting `max_allowed_packet`, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

22.2.5.10.2. Writing a File to the Database

To write a file to a database, we need to convert the file to a byte array, then use the byte array as a parameter to an `INSERT` query.

The following code opens a file using a `FileStream` object, reads it into a byte array, and inserts it into the `file` table:

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim fileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
    fileSize = fs.Length

    rawData = New Byte(fileSize) {}
    fs.Read(rawData, 0, fileSize)
    fs.Close()

    conn.Open()

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)"

    cmd.Connection = conn
    cmd.CommandText = SQL
    cmd.Parameters.AddWithValue("@FileName", strFileName)
    cmd.Parameters.AddWithValue("@FileSize", fileSize)
    cmd.Parameters.AddWithValue("@File", rawData)

    cmd.ExecuteNonQuery()

    MessageBox.Show("File Inserted into database successfully!", _
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", _
        MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();
```

```

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
    FileSize = fs.Length;

    rawData = new byte[FileSize];
    fs.Read(rawData, 0, FileSize);
    fs.Close();

    conn.Open();

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)";

    cmd.Connection = conn;
    cmd.CommandText = SQL;
    cmd.Parameters.AddWithValue("@FileName", strFileName);
    cmd.Parameters.AddWithValue("@FileSize", FileSize);
    cmd.Parameters.AddWithValue("@File", rawData);

    cmd.ExecuteNonQuery();

    MessageBox.Show("File Inserted into database successfully!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The `Read` method of the `FileStream` object is used to load the file into a byte array which is sized according to the `Length` property of the `FileStream` object.

After assigning the byte array as a parameter of the `MySqlCommand` object, the `ExecuteNonQuery` method is called and the `BLOB` is inserted into the `file` table.

22.2.5.10.3. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySqlDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

Visual Basic Example

```

Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySqlDataReader
Dim SQL As String
Dim rawData() As Byte
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _

```

```

    & "pwd=12345;" _
    & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
    conn.Open()

    cmd.Connection = conn
    cmd.CommandText = SQL

    myData = cmd.ExecuteReader

    If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

    myData.Read()

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
    rawData = New Byte(FileSize) {}

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

    fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
    fs.Write(rawData, 0, FileSize)
    fs.Close()

    MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK, MessageBoxIcon.Ast

    myData.Close()
    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

C# Example

```

MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;
MySQL.Data.MySqlClient.MySqlDataReader myData;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
    conn.Open();

    cmd.Connection = conn;
    cmd.CommandText = SQL;

    myData = cmd.ExecuteReader();

    if (! myData.HasRows)
        throw new Exception("There are no BLOBs to save");

    myData.Read();

```

```

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
    rawData = new byte[FileSize];

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, (int)FileSize);

    fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
    fs.Write(rawData, 0, (int)FileSize);
    fs.Close();

    MessageBox.Show("File successfully written to disk!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    myData.Close();
    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the `MySqlDataReader` is used to load the `BLOB` into a byte array, which is then written to disk using a `FileStream` object.

The `GetOrdinal` method of the `MySqlDataReader` can be used to determine the integer index of a named column. Use of the `GetOrdinal` method prevents errors if the column order of the `SELECT` query is changed.

22.2.5.11. Using the Connector/Net Interceptor Classes

An interceptor is a software design pattern that provides a transparent way to extend or modify some aspect of a program, similar to a user exit. No recompiling is required. With Connector/Net, the interceptors are enabled and disabled by updating the connection string to refer to different sets of interceptor classes that you instantiate.

Connector/Net includes the following interceptor classes:

- The `BaseCommandInterceptor` lets you perform additional operations when a program issues a SQL command. For example, you can examine the SQL statement for logging or debugging purposes, substitute your own result set to implement a caching mechanism, and so on. Depending on the use case, your code can supplement the SQL command or replace it entirely.

The `BaseCommandInterceptor` class has these methods that you can override:

```

public virtual bool ExecuteScalar(string sql, ref object returnValue);
public virtual bool ExecuteNonQuery(string sql, ref int returnValue);
public virtual bool ExecuteReader(string sql, CommandBehavior behavior, ref MySqlDataReader returnValue);
public virtual void Init(MySqlConnection connection);

```

If your interceptor overrides one of the `Execute...` methods, set the `returnValue` output parameter and return `true` if you handled the event, or `false` if you did not handle the event. The SQL command is processed normally only when all command interceptors return `false`.

The connection passed to the `Init` method is the connection that is attached to this interceptor.

- The `BaseExceptionInterceptor` lets you perform additional operations when a program encounters a SQL exception. The exception interception mechanism is modeled after the Connector/J model. You can code an interceptor class and connect it to an existing program without recompiling, and intercept exceptions when they are created. You can then change the exception type and optionally attach information to it. This capability lets you turn on and off logging and debugging code without hardcoding

anything in the application. This technique applies to exceptions raised at the SQL level, not to lower-level system or I/O errors.

You develop an exception interceptor first by creating a subclass of the `BaseExceptionInterceptor` class. You must override the `InterceptException()` method. You can also override the `Init()` method to do some one-time initialization.

Each exception interceptor has 2 methods:

```
public abstract Exception InterceptException(Exception exception,
    MySqlConnection connection);
public virtual void Init(MySqlConnection connection);
```

The connection passed to `Init()` is the connection that is attached to this interceptor.

Each interceptor is required to override `InterceptException` and return an exception. It can return the exception it is given, or it can wrap it in a new exception. We currently do not offer the ability to suppress the exception.

Here are examples of using the FQN (fully qualified name) on the connection string:

```
MySqlConnection c1 = new MySqlConnection(@"server=localhost;pooling=false;
commandinterceptors=CommandApp.MyCommandInterceptor,CommandApp");

MySqlConnection c2 = new MySqlConnection(@"server=localhost;pooling=false;
exceptioninterceptors=ExceptionStackTraceTest.MyExceptionInterceptor,ExceptionStackTraceTest");
```

In this example, the command interceptor is called `CommandApp.MyCommandInterceptor` and exists in the `CommandApp` assembly. The exception interceptor is called `ExceptionStackTraceTest.MyExceptionInterceptor` and exists in the `ExceptionStackTraceTest` assembly.

To shorten the connection string, you can register your exception interceptors in your `app.config` or `web.config` file like this:

```
<configSections>
<section name="MySQL" type="MySQL.Data.MySqlClient.MySqlConfiguration,
MySQL.Data"/>
</configSections>
<MySQL>
<CommandInterceptors>
  <add name="myC" type="CommandApp.MyCommandInterceptor,CommandApp" />
</CommandInterceptors>
</MySQL>

<configSections>
<section name="MySQL" type="MySQL.Data.MySqlClient.MySqlConfiguration,
MySQL.Data"/>
</configSections>
<MySQL>
<ExceptionInterceptors>
  <add name="myE"
type="ExceptionStackTraceTest.MyExceptionInterceptor,ExceptionStackTraceTest" />
</ExceptionInterceptors>
</MySQL>
```

Once you have done that, your connection strings can look like these:

```
MySqlConnection c1 = new MySqlConnection(@"server=localhost;pooling=false;
commandinterceptors=myC");
```

```
MySQLConnection c2 = new MySQLConnection(@"server=localhost;pooling=false;  
exceptioninterceptors=myE");
```

22.2.5.12. Handling Date and Time Information in Connector/Net

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '0000-00-00 00:00:00'. These differences can cause problems if not properly handled.

The following sections demonstrate how to properly handle date and time information when using Connector/Net.

22.2.5.12.1. Fractional Seconds

Connector/Net 6.5 and higher support the fractional seconds feature introduced in MySQL 5.6.4. Fractional seconds could always be specified in a date literal or passed back and forth as parameters and return values, but the fractional part was always stripped off when stored in a table column. In MySQL 5.6.4 and higher, the fractional part is now preserved in data stored and retrieved through SQL. For fractional second handling in MySQL 5.6.4 and higher, see [Fractional Seconds in Time Values](#). For the behavior of fractional seconds prior to MySQL 5.6.4, see [Section 11.3.6, "Fractional Seconds in Time Values"](#).

To use the more precise date and time types, specify a value from 1 to 6 when creating the table column, for example `TIME(3)` or `DATETIME(6)`, representing the number of digits of precision after the decimal point. Specifying a precision of 0 leaves the fractional part out entirely. In your C# or Visual Basic code, refer to the `Millisecond` member to retrieve the fractional second value from the `MySQLDateTime` object returned by the `GetMySQLDateTime` function. The `DateTime` object returned by the `GetDateTime` function also contains the fractional value, but only the first 3 digits.

For related code examples, see the following blog post: https://blogs.oracle.com/MySQLOnWindows/entry/milliseconds_value_support_on_datetime

22.2.5.12.2. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySQLDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

22.2.5.12.3. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see [Section 5.1.7, "Server SQL Modes"](#).

22.2.5.12.4. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySQLDateTime` data type.

The `MySqlDateTime` data type supports the same date values that are supported by the MySQL server. The default behavior of Connector/Net is to return a .NET `DateTime` object for valid date values, and return an error for invalid dates. This default can be modified to cause Connector/Net to return `MySqlDateTime` objects for invalid dates.

To instruct Connector/Net to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, 2005-02-23 08:50:25). This differs from the `ToString` behavior of the .NET `DateTime` class.
3. The `MySqlDateTime` class supports NULL dates, while the .NET `DateTime` class does not. This can cause errors when trying to convert a `MySqlDateTime` to a `DateTime` if you do not check for NULL first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

22.2.5.12.5. Handling NULL Dates

The .NET `DateTime` data type cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

Visual Basic Example

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
    myTime = DateTime.MinValue
End If
```

C# Example

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
    myTime = DateTime.MinValue;
```

`NULL` values will work in a data set and can be bound to form controls without special handling.

22.2.5.13. Using the `MySqlBulkLoader` Class

MySQL Connector/Net features a bulk loader class that wraps the MySQL statement `LOAD DATA INFILE`. This gives MySQL Connector/Net the ability to load a data file from a local or remote host to the server. The class concerned is `MySqlBulkLoader`. This class has various methods, the main one being `load` to cause the specified file to be loaded to the server. Various parameters can be set to control how the data file is processed. This is achieved through setting various properties of the class. For example, the field separator used, such as comma or tab, can be specified, along with the record terminator, such as newline.

The following code shows a simple example of using the `MySQLBulkLoader` class. First an empty table needs to be created, in this case in the `test` database:

```
CREATE TABLE Career (
    Name VARCHAR(100) NOT NULL,
    Age INTEGER,
    Profession VARCHAR(200)
);
```

A simple tab-delimited data file is also created (it could use any other field delimiter such as comma):

```
Table Career in Test Database
Name Age Profession

Tony 47 Technical Writer
Ana 43 Nurse
Fred 21 IT Specialist
Simon 45 Hairy Biker
```

Note that with this test file the first three lines will need to be ignored, as they do not contain table data. This can be achieved using the `NumberOfLinesToSkip` property. This file can then be loaded and used to populate the `Career` table in the `test` database:

```
using System;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=test;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            MySQLBulkLoader bl = new MySQLBulkLoader(conn);
            bl.TableName = "Career";
            bl.FieldTerminator = "\t";
            bl.LineTerminator = "\n";
            bl.FileName = "c:/career_data.txt";
            bl.NumberOfLinesToSkip = 3;

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                // Upload data from file
                int count = bl.Load();
                Console.WriteLine(count + " lines uploaded.");

                string sql = "SELECT Name, Age, Profession FROM Career";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1] + " -- " + rdr[2]);
                }

                rdr.Close();
                conn.Close();
            }
        }
    }
}
```

```

    }
    catch (Exception ex)
    {
        Console.WriteLine(ex.ToString());
    }
    Console.WriteLine("Done.");
}
}
}

```

Further information on [LOAD DATA INFILE](#) can be found in [Section 13.2.6, "LOAD DATA INFILE Syntax"](#). Further information on [MySqlBulkLoader](#) can be found in the reference documentation that was included with your connector.

22.2.5.14. Using the MySQL Connector/Net Trace Source Object

MySQL Connector/Net 6.2 introduced support for .NET 2.0 compatible tracing, using [TraceSource](#) objects.

The .NET 2.0 tracing architecture consists of four main parts:

- *Source* - This is the originator of the trace information. The source is used to send trace messages. The name of the source provided by MySQL Connector/Net is [mysql](#).
- *Switch* - This defines the level of trace information to emit. Typically, this is specified in the [app.config](#) file, so that it is not necessary to recompile an application to change the trace level.
- *Listener* - Trace listeners define where the trace information will be written to. Supported listeners include, for example, the Visual Studio Output window, the Windows Event Log, and the console.
- *Filter* - Filters can be attached to listeners. Filters determine the level of trace information that will be written. While a switch defines the level of information that will be written to all listeners, a filter can be applied on a per-listener basis, giving finer grained control of trace information.

To use tracing a [TraceSource](#) object first needs to be created. To create a [TraceSource](#) object in MySQL Connector/Net you would use code similar to the following:

```
TraceSource ts = new TraceSource("mysql");
```

To enable trace messages, configure a trace switch. There are three main switch classes, [BooleanSwitch](#), [SourceSwitch](#), and [TraceSwitch](#). Trace switches also have associated with them a trace level enumeration, these are [Off](#), [Error](#), [Warning](#), [Info](#), and [Verbose](#). The following code snippet illustrates creating a switch:

```
ts.Switch = new SourceSwitch("MySwitch", "Verbose");
```

This creates a [SourceSwitch](#), called [MySwitch](#), and sets the trace level to [Verbose](#), meaning that all trace messages will be written.

It is convenient to be able to change the trace level without having to recompile the code. This is achieved by specifying the trace level in application configuration file, [app.config](#). You then simply need to specify the desired trace level in the configuration file and restart the application. The trace source is configured within the [system.diagnostics](#) section of the file. The following XML snippet illustrates this:

```

<configuration>
  ...
  <system.diagnostics>
    <sources>

```

```

    <source name="mysql" switchName="MySwitch"
           switchType="System.Diagnostics.SourceSwitch" />
    ...
  </sources>
  <switches>
    <add name="MySwitch" value="Verbose" />
    ...
  </switches>
</system.diagnostics>
...
</configuration>

```

By default, trace information is written to the Output window of Microsoft Visual Studio. There are a wide range of listeners that can be attached to the trace source, so that trace messages can be written out to various destinations. You can also create custom listeners to allow trace messages to be written to other destinations as mobile devices and web services. A commonly used example of a listener is [ConsoleTraceListener](#), which writes trace messages to the console.

To add a listener at run time, use code such as the following:

```
ts.Listeners.Add(new ConsoleTraceListener());
```

Then, call methods on the trace source object to generate trace information. For example, the [TraceInformation\(\)](#), [TraceEvent\(\)](#), or [TraceData\(\)](#) methods can be used.

The [TraceInformation\(\)](#) method simply prints a string passed as a parameter. The [TraceEvent\(\)](#) method, as well as the optional informational string, requires a [TraceEventType](#) value to be passed to indicate the trace message type, and also an application specific ID. The [TraceEventType](#) can have a value of [Verbose](#), [Information](#), [Warning](#), [Error](#), and [Critical](#). Using the [TraceData\(\)](#) method you can pass any object, for example an exception object, instead of a message.

To ensure that these generated trace messages gets flushed from the trace source buffers to listeners, invoke the [Flush\(\)](#) method. When you are finished using a trace source, call the [Close\(\)](#) method. The [Close\(\)](#) method first calls [Flush\(\)](#), to ensure any remaining data is written out. It then frees up resources, and closes the listeners associated with the trace source.

```

ts.TraceInformation("Informational message");
ts.TraceEvent(TraceEventType.Error, 3, "Optional error message");
ts.TraceData(TraceEventType.Error, 3, ex); // pass exception object
ts.Flush();
...
ts.Close();

```

22.2.5.14.1. Viewing MySQL Trace Information

This section describes how to set up your application to view MySQL trace information.

The first thing you need to do is create a suitable [app.config](#) file for your application. An example is shown in the following code:

```

<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <system.diagnostics>
    <sources>
      <source name="mysql" switchName="SourceSwitch"
             switchType="System.Diagnostics.SourceSwitch" >
        <listeners>
          <add name="console" />
          <remove name="Default" />
        </listeners>
      </source>
    </sources>
  </system.diagnostics>
</configuration>

```

```
</source>
</sources>
<switches>
  <!-- You can set the level at which tracing is to occur -->
  <add name="SourceSwitch" value="Verbose" />
  <!-- You can turn tracing off -->
  <!--add name="SourceSwitch" value="Off" -->
</switches>
<sharedListeners>
  <add name="console"
    type="System.Diagnostics.ConsoleTraceListener"
    initializeData="false"/>
</sharedListeners>
</system.diagnostics>
</configuration>
```

This ensures a suitable trace source is created, along with a switch. The switch level in this case is set to [Verbose](#) to display the maximum amount of information.

In the application the only other step required is to add `logging=true` to the connection string. An example application could be:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Diagnostics;
using MySql.Data;
using MySql.Data.MySqlClient;
using MySql.Web;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=world;port=3306;password=*****;logging=true";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1]);
                }

                rdr.Close();

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}
```

```
}

```

This simple application will then generate the following output:

```
Connecting to MySQL...
mysql Information: 1 : 1: Connection Opened: connection string = 'server=localhost;User Id=root;database=world;password=*****;logging=True'
mysql Information: 3 : 1: Query Opened: SHOW VARIABLES
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=272, skipped rows=0, size (bytes)=7058
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SHOW COLLATION
mysql Information: 4 : 1: Resultset Opened: field(s) = 6, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=127, skipped rows=0, size (bytes)=4102
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SET character_set_results=NULL
mysql Information: 4 : 1: Resultset Opened: field(s) = 0, affected rows = 0, inserted id = 0
mysql Information: 5 : 1: Resultset Closed. Total rows=0, skipped rows=0, size (bytes)=0
mysql Information: 6 : 1: Query Closed
mysql Information: 10 : 1: Set Database: world
mysql Information: 3 : 1: Query Opened: SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
American Samoa -- George W. Bush
Australia -- Elisabeth II
...
Wallis and Futuna -- Jacques Chirac
Vanuatu -- John Bani
United States Minor Outlying Islands -- George W. Bush
mysql Information: 5 : 1: Resultset Closed. Total rows=28, skipped rows=0, size (bytes)=788
mysql Information: 6 : 1: Query Closed
Done.
mysql Information: 2 : 1: Connection Closed
```

The first number displayed in the trace message corresponds to the MySQL event type:

| Event | Description |
|-------|---|
| 1 | ConnectionOpened: connection string |
| 2 | ConnectionClosed: |
| 3 | QueryOpened: mysql server thread id, query text |
| 4 | ResultOpened: field count, affected rows (-1 if select), inserted id (-1 if select) |
| 5 | ResultClosed: total rows read, rows skipped, size of resultset in bytes |
| 6 | QueryClosed: |
| 7 | StatementPrepared: prepared sql, statement id |
| 8 | StatementExecuted: statement id, mysql server thread id |
| 9 | StatementClosed: statement id |
| 10 | NonQuery: [varies] |
| 11 | UsageAdvisorWarning: usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5. |
| 12 | Warning: level, code, message |
| 13 | Error: error number, error message |

The second number displayed in the trace message is the connection count.

Although this example uses the `ConsoleTraceListener`, any of the other standard listeners could have been used. Another possibility is to create a custom listener that uses the information passed using the `TraceEvent` method. For example, a custom trace listener could be created to perform active monitoring of the MySQL event messages, rather than simply writing these to an output device.

It is also possible to add listeners to the MySQL Trace Source at run time. This can be done with the following code:

```
MySQLTrace.Listeners.Add(new ConsoleTraceListener());
```

MySQL Connector/Net 6.3.2 introduced the ability to switch tracing on and off at run time. This can be achieved using the calls `MySQLTrace.EnableQueryAnalyzer(string host, int postInterval)` and `MySQLTrace.DisableQueryAnalyzer()`. The parameter `host` is the URL of the MySQL Enterprise Monitor server to monitor. The parameter `postInterval` is how often to post the data to MySQL Enterprise Monitor, in seconds.

22.2.5.14.2. Building Custom Listeners

To build custom listeners that work with the MySQL Connector/Net Trace Source, it is necessary to understand the key methods used, and the event data formats used.

The main method involved in passing trace messages is the `TraceSource.TraceEvent` method. This has the prototype:

```
public void TraceEvent(  
    TraceEventType eventType,  
    int id,  
    string format,  
    params Object[] args  
)
```

This trace source method will process the list of attached listeners and call the listener's `TraceListener.TraceEvent` method. The prototype for the `TraceListener.TraceEvent` method is as follows:

```
public virtual void TraceEvent(  
    TraceEventCache eventCache,  
    string source,  
    TraceEventType eventType,  
    int id,  
    string format,  
    params Object[] args  
)
```

The first three parameters are used in the standard as [defined by Microsoft](#). The last three parameters contain MySQL-specific trace information. Each of these parameters is now discussed in more detail.

`int id`

This is a MySQL-specific identifier. It identifies the MySQL event type that has occurred, resulting in a trace message being generated. This value is defined by the `MySQLTraceEventType` public enum contained in the MySQL Connector/Net code:

```
public enum MySQLTraceEventType : int  
{  
    ConnectionOpened = 1,  
    ConnectionClosed,  
    QueryOpened,  
    ResultOpened,  
    ResultClosed,  
    QueryClosed,  
}
```

```

StatementPrepared,
StatementExecuted,
StatementClosed,
NonQuery,
UsageAdvisorWarning,
Warning,
Error
}

```

The MySQL event type also determines the contents passed using the parameter `params Object[] args`. The nature of the `args` parameters are described in further detail in the following material.

string format

This is the format string that contains zero or more format items, which correspond to objects in the `args` array. This would be used by a listener such as `ConsoleTraceListener` to write a message to the output device.

params Object[] args

This is a list of objects that depends on the MySQL event type, `id`. However, the first parameter passed using this list is always the driver id. The driver id is a unique number that is incremented each time the connector is opened. This enables groups of queries on the same connection to be identified. The parameters that follow driver id depend on the MySQL event id, and are as follows:

| MySQL-specific event type | Arguments (params Object[] args) |
|---------------------------|--|
| ConnectionOpened | Connection string |
| ConnectionClosed | No additional parameters |
| QueryOpened | mysql server thread id, query text |
| ResultOpened | field count, affected rows (-1 if select), inserted id (-1 if select) |
| ResultClosed | total rows read, rows skipped, size of resultset in bytes |
| QueryClosed | No additional parameters |
| StatementPrepared | prepared sql, statement id |
| StatementExecuted | statement id, mysql server thread id |
| StatementClosed | statement id |
| NonQuery | Varies |
| UsageAdvisorWarning | usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5. |
| Warning | level, code, message |
| Error | error number, error message |

This information will allow you to create custom trace listeners that can actively monitor the MySQL-specific events.

22.2.5.15. Binary/Nonbinary Issues

There are certain situations where MySQL will return incorrect metadata about one or more columns. More specifically, the server will sometimes report that a column is binary when it is not and vice versa. In these situations, it becomes practically impossible for the connector to be able to correctly identify the correct metadata.

Some examples of situations that may return incorrect metadata are:

- Execution of `SHOW PROCESSLIST`. Some of the columns will be returned as binary even though they only hold string data.
- When a temporary table is used to process a resultset, some columns may be returned with incorrect binary flags.
- Some server functions such `DATE_FORMAT` will incorrectly return the column as binary.

With the availability of `BINARY` and `VARBINARY` data types, it is important that we respect the metadata returned by the server. However, we are aware that some existing applications may break with this change, so we are creating a connection string option to enable or disable it. By default, Connector/Net 5.1 respects the binary flags returned by the server. You might need to make small changes to your application to accommodate this change.

In the event that the changes required to your application would be too large, adding `'respect binary flags=false'` to your connection string causes the connector to use the prior behavior: any column that is marked as string, regardless of binary flags, will be returned as string. Only columns that are specifically marked as a `BLOB` will be returned as `BLOB`.

22.2.5.16. Character Set Considerations for Connector/Net

Treating Binary Blobs As UTF8

MySQL doesn't currently support 4-byte UTF8 sequences. This makes it difficult to represent some multi-byte languages such as Japanese. To try and alleviate this, Connector/Net now supports a mode where binary blobs can be treated as strings.

To do this, you set the `'Treat Blobs As UTF8'` connection string keyword to `yes`. This is all that needs to be done to enable conversion of all binary blobs to UTF8 strings. To convert only some of your BLOB columns, you can make use of the `'BlobAsUTF8IncludePattern'` and `'BlobAsUTF8ExcludePattern'` keywords. Set these to a regular expression pattern that matches the column names to include or exclude respectively.

When the regular expression patterns both match a single column, the include pattern is applied before the exclude pattern. The result, in this case, would be that the column would be excluded. Also, be aware that this mode does not apply to columns of type `BINARY` or `VARBINARY` and also do not apply to nonbinary `BLOB` columns.

Currently, this mode only applies to reading strings out of MySQL. To insert 4-byte UTF8 strings into blob columns, use the `.NET Encoding.GetBytes` function to convert your string to a series of bytes. You can then set this byte array as a parameter for a `BLOB` column.

22.2.5.17. Using Connector/Net with Crystal Reports

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/Net.

22.2.5.17.1. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a data set that matches the one expected by your report.

The second option is to create a data set in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the data set. If you forget a column you must re-create the data set before the column can be added to the report.

The following code can be used to create a data set from a query and write it to disk:

Visual Basic Example

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from dev.mysql.com.

22.2.5.17.2. Creating the Report

For most purposes, the Standard Report wizard helps with the initial creation of a report. To start the wizard, open Crystal Reports and choose the **New > Standard Report** option from the File menu.

The wizard first prompts you for a data source. If you use Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved data set, choose the ADO.NET (XML) option and browse to your saved data set.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

22.2.5.17.3. Displaying the Report

To display a report we first populate a data set with the data needed for the report, then load the report and bind it to the data set. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrystalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a data set saved using the code shown in [Section 22.2.5.17.1, "Creating a Data Source"](#), and have a crViewer control on your form named `myViewer`.

Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _
    "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()
```

```

cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
    & "country.name, country.population, country.continent " _
    & "FROM country, city ORDER BY country.continent, country.name"
cmd.Connection = conn

myAdapter.SelectCommand = cmd
myAdapter.Fill(myData)

myReport.Load(".\world_report.rpt")
myReport.SetDataSource(myData)
myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try

```

C# Example

```

using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.SetDataSource(myData);
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

A new data set is generated using the same query used to generate the previously saved data set. Once the data set is filled, a ReportDocument is used to load the report file and bind it to the data set. The ReportDocument is then passed as the ReportSource of the crViewer.

This same approach is taken when a report is created from a single table using Connector/ODBC. The data set replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a data set with multiple tables must be created in our application. This enables each table in the report data source to be replaced with a report in the data set.

We populate a data set with multiple tables by providing multiple `SELECT` statements in our `MySqlCommand` object. These `SELECT` statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```
SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.`Name`, `city`.`Population`
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `country`.`Code`=`city`.`CountryCode`
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`
```

This query is converted to two `SELECT` queries and displayed with the following code:

Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY countrycode, name;" _
        & "SELECT name, population, code, continent FROM country ORDER BY continent, name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
```

```

        "BY countrycode, name; SELECT name, population, code, continent FROM " +
        "country ORDER BY continent, name";
        cmd.Connection = conn;

        myAdapter.SelectCommand = cmd;
        myAdapter.Fill(myData);

        myReport.Load(@".\world_report.rpt");
        myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
        myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
        myViewer.ReportSource = myReport;
    }
    catch (MySql.Data.MySqlClient.MySqlException ex)
    {
        MessageBox.Show(ex.Message, "Report could not be created",
            MessageBoxButtons.OK, MessageBoxIcon.Error);
    }
}

```

It is important to order the `SELECT` queries in alphabetic order, as this is the order the report will expect its source tables to be in. One `SetDataSource` statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved data set.

22.2.5.18. ASP.NET Provider Model

MySQL Connector/Net provides support for the ASP.NET 2.0 provider model. This model enables application developers to focus on the business logic of their application instead of having to recreate such boilerplate items as membership and roles support.

MySQL Connector/Net supplies the following providers:

- Membership Provider
- Role Provider
- Profile Provider
- Session State Provider (MySQL Connector/Net 6.1 and later)

The following tables show the supported providers, their default provider and the corresponding MySQL provider.

Membership Provider

| Default Provider | MySQL Provider |
|---|--|
| System.Web.Security.SqlMembershipProvider | MySql.Web.Security.MySQLMembershipProvider |

Role Provider

| Default Provider | MySQL Provider |
|-------------------------------------|--------------------------------------|
| System.Web.Security.SqlRoleProvider | MySql.Web.Security.MySQLRoleProvider |

Profile Provider

| Default Provider | MySQL Provider |
|---------------------------------------|--|
| System.Web.Profile.SqlProfileProvider | MySql.Web.Profile.MySQLProfileProvider |

SessionState Provider

| Default Provider | MySQL Provider |
|---|---|
| System.Web.SessionState.InProcSessionStateStore | MySql.Web.SessionState.MySqlSessionStateStore |

Note

The MySQL Session State provider uses slightly different capitalization on the class name compared to the other MySQL providers.

Installing The Providers

The installation of Connector/Net 5.1 or later will install the providers and register them in your machine's .NET configuration file, `machine.config`. The additional entries created will result in the `system.web` section appearing similar to the following code:

```
<system.web>
  <processModel autoConfig="true" />
  <httpHandlers />
  <membership>
    <providers>
      <add name="AspNetSqlMembershipProvider" type="System.Web.Security.SqlMembershipProvider, System.Web, Ver
      <add name="MySQLMembershipProvider" type="MySql.Web.Security.MySQLMembershipProvider, MySql.Web, Version
    </providers>
  </membership>
  <profile>
    <providers>
      <add name="AspNetSqlProfileProvider" connectionStringName="LocalSqlServer" applicationName="/" type="Sys
      <add name="MySQLProfileProvider" type="MySql.Web.Profile.MySQLProfileProvider, MySql.Web, Version=6.1.1.
    </providers>
  </profile>
  <roleManager>
    <providers>
      <add name="AspNetSqlRoleProvider" connectionStringName="LocalSqlServer" applicationName="/" type="System
      <add name="AspNetWindowsTokenRoleProvider" applicationName="/" type="System.Web.Security.WindowsTokenRol
      <add name="MySQLRoleProvider" type="MySql.Web.Security.MySQLRoleProvider, MySql.Web, Version=6.1.1.0, Cu
    </providers>
  </roleManager>
</system.web>
```

Each provider type can have multiple provider implementations. The default provider can also be set here using the `defaultProvider` attribute, but usually this is set in the `web.config` file either manually or by using the ASP.NET configuration tool.

At time of writing, the `MySqlSessionStateStore` is not added to `machine.config` at install time, and so add the following:

```
<sessionState>
  <providers>
    <add name="MySqlSessionStateStore" type="MySql.Web.SessionState.MySqlSessionStateStore, MySql.Web, Version
  </providers>
</sessionState>
```

The SessionState Provider uses the `customProvider` attribute, rather than `defaultProvider`, to set the provider as the default. A typical `web.config` file might contain:

```
<system.web>
  <membership defaultProvider="MySQLMembershipProvider" />
  <roleManager defaultProvider="MySQLRoleProvider" />
  <profile defaultProvider="MySQLProfileProvider" />
  <sessionState customProvider="MySqlSessionStateStore" />
  <compilation debug="false">
```

...

This sets the MySQL Providers as the defaults to be used in this web application.

The providers are implemented in the file `mysql.web.dll` and this file can be found in your MySQL Connector/Net installation folder. There is no need to run any type of SQL script to set up the database schema, as the providers create and maintain the proper schema automatically.

Using The Providers

The easiest way to start using the providers is to use the ASP.NET configuration tool that is available on the Solution Explorer toolbar when you have a website project loaded.

In the web pages that open, you can select the MySQL membership and roles providers by picking a custom provider for each area.

When the provider is installed, it creates a dummy connection string named `LocalMySqlServer`. Although this has to be done so that the provider will work in the ASP.NET configuration tool, you override this connection string in your `web.config` file. You do this by first removing the dummy connection string and then adding in the proper one, as shown in the following example:

```
<connectionStrings>
  <remove name="LocalMySqlServer" />
  <add name="LocalMySqlServer" connectionString="server=xxx;uid=xxx;pwd=xxx;database=xxx;" />
</connectionStrings>
```

Note the database to connect to must be specified.

Rather than manually editing configuration files, consider using the MySQL Website Configuration tool to configure your desired provider setup. From MySQL Connector/Net 6.1.1 onwards, all providers can be selected and configured from this wizard. The tool modifies your `website.config` file to the desired configuration. A tutorial on doing this is available in the following section [Section 22.2.3.12, "MySQL Website Configuration Tool"](#).

A tutorial demonstrating how to use the Membership and Role Providers can be found in the following section [Section 22.2.4.2, "Tutorial: MySQL Connector/Net ASP.NET Membership and Role Provider"](#).

Deployment

To use the providers on a production server, distribute the `MySql.Data` and the `MySql.Web` assemblies, and either register them in the remote systems Global Assembly Cache or keep them in your application's `bin/` directory.

22.2.5.19. Working with Partial Trust / Medium Trust

.NET applications operate under a given trust level. Normal desktop applications operate under full trust, while web applications that are hosted in shared environments are normally run under the partial trust level (also known as "medium trust"). Some hosting providers host shared applications in their own app pools and allow the application to run under full trust, but this configuration is relatively rare. The Connector/Net support for partial trust has improved over time to simplify the configuration and deployment process for hosting providers.

22.2.5.19.1. Evolution of Partial Trust Support Across Connector/Net Versions

The partial trust support for Connector/Net has improved rapidly throughout the 6.5.x and 6.6.x versions. The latest enhancements do require some configuration changes in existing deployments. Here is a summary of the changes for each version.

6.6.4 and Above: Library Can Be Inside or Outside GAC

Now you can install the `MySql.Data.dll` library in the Global Assembly Cache (GAC) as explained in [Section 22.2.5.19.2, “Configuring Partial Trust with Connector/Net Library Installed in GAC”](#), or in a `bin` or `lib` folder inside the project or solution as explained in [Section 22.2.5.19.3, “Configuring Partial Trust with Connector/Net Library Not Installed in GAC”](#). If the library is not in the GAC, the only protocol supported is TCP/IP.

6.5.1 and Above: Partial Trust Requires Library in the GAC

Connector/Net 6.5 fully enables our provider to run in a partial trust environment when the library is installed in the Global Assembly Cache (GAC). The new `MySqlClientPermission` class, derived from the .NET `DBDataPermission` class, helps to simplify the permission setup.

5.0.8 / 5.1.3 and Above: Partial Trust Requires Socket Permissions

Starting with these versions, Connector/Net can be used under partial trust hosting that has been modified to allow the use of sockets for communication. By default, partial trust does not include `SocketPermission`. Connector/Net uses sockets to talk with the MySQL server, so the hosting provider must create a new trust level that is an exact clone of partial trust but that has the following permissions added:

- `System.Net.SocketPermission`
- `System.Security.Permissions.ReflectionPermission`
- `System.Net.DnsPermission`
- `System.Security.Permissions.SecurityPermission`

Prior to 5.0.8 / 5.1.3: Partial Trust Not Supported

Connector/Net versions prior to 5.0.8 and 5.1.3 were not compatible with partial trust hosting.

22.2.5.19.2. Configuring Partial Trust with Connector/Net Library Installed in GAC

If the library is installed in the GAC, you must include the connection option `includesecurityasserts=true` in your connection string. This is a new requirement as of Connector/Net 6.6.4.

The following list shows steps and code fragments needed to run a Connector/Net application in a partial trust environment. For illustration purposes, we use the Pipe Connections protocol in this example.

1. Install Connector/Net: version 6.6.1 or higher, or 6.5.4 or higher.
2. After installing the library, make the following configuration changes:

In the `SecurityClasses` section, add a definition for the `MySqlClientPermission` class, including the version to use.

```
<configuration>
  <mscorlib>
    <security>
      <policy>
        <PolicyLevel version="1">
          <SecurityClasses>
            ....
            <SecurityClass Name="MySqlClientPermission" Description="MySql.Data.MySqlClient.MySqlClientPerm
```

Scroll down to the `ASP.Net` section:

```
<PermissionSet class="NamedPermissionSet" version="1" Name="ASP.Net">
```

Add a new entry for the detailed configuration of the `MySQLClientPermission` class:

```
<IPermission class="MySQLClientPermission" version="1" Unrestricted="true"/>
```

Note: This configuration is the most generalized way that includes all keywords.

3. Configure the MySQL server to accept pipe connections, by adding the `--enable-named-pipe` option on the command line. If you need more information about this, see [Section 2.3, "Installing MySQL on Microsoft Windows"](#).
4. Confirm that the hosting provider has installed the Connector/Net library (`MySQL.Data.dll`) in the GAC.
5. Optionally, the hosting provider can avoid granting permissions globally by using the new `MySQLClientPermission` class in the trust policies. (The alternative is to globally enable the permissions `System.Net.SocketPermission`, `System.Security.Permissions.ReflectionPermission`, `System.Net.DnsPermission`, and `System.Security.Permissions.SecurityPermission`.)
6. Create a simple web application using Visual Studio 2010.
7. Add the reference in your application for the `MySQL.Data.MySqlClient` library.
8. Edit your `web.config` file so that your application runs using a Medium trust level:

```
<system.web>
  <trust level="Medium"/>
</system.web>
```

9. Add the `MySQL.Data.MySqlClient` namespace to your server-code page.
10. Define the connection string, in slightly different ways depending on the Connector/Net version.

Only for 6.6.4 or later: To use the connections inside any web application that will run in Medium trust, add the new `includesecurityasserts` option to the connection string. `includesecurityasserts=true` that makes the library request the following permissions when required: `SocketPermissions`, `ReflectionPermissions`, `DnsPermissions`, `SecurityPermissions` among others that are not granted in Medium trust levels.

For Connector/Net 6.6.3 or earlier: No special setting for security is needed within the connection string.

```
MySQLConnectionStringBuilder myconnString = new MySQLConnectionStringBuilder("server=localhost;User Id=
myconnString.PipeName = "MySQL55";
myconnString.ConnectionProtocol = MySQLConnectionProtocol.Pipe;
// Following attribute is a new requirement when the library is in the GAC.
// Could also be done by adding includesecurityasserts=true; to the string literal
// in the constructor above.
// Not needed with Connector/Net 6.6.3 and earlier.myconnString.IncludeSecurityAsserts = true;
```

11. Define the `MySQLConnection` to use:

```
MySQLConnection myconn = new MySQLConnection(myconnString.ConnectionString);
myconn.Open();
```

12. Retrieve some data from your tables:

```
MySqlCommand cmd = new MySqlCommand("Select * from products", myconn);
MySqlDataAdapter da = new MySqlDataAdapter(cmd);
DataSet1 tds = new DataSet1();
da.Fill(tds, tds.Tables[0].TableName);
GridView1.DataSource = tds;
GridView1.DataBind();
myconn.Close();
```

13. Run the program. It should execute successfully, without requiring any special code or encountering any security problems.

22.2.5.19.3. Configuring Partial Trust with Connector/Net Library Not Installed in GAC

When deploying a web application to a Shared Hosted environment, where this environment is configured to run all their .NET applications under a partial or medium trust level, you might not be able to install the Connector/Net library in the GAC. Instead, you put a reference to the library in the `bin` or `lib` folder inside the project or solution. In this case, you configure the security in a different way than when the library is in the GAC.

Connector/Net is commonly used by applications that run in Windows environments where the default communication for the protocol is used via sockets or by TCP/IP. For this protocol to operate is necessary have the required socket permissions in the web configuration file as follows:

1. Open the medium trust policy web configuration file, which should be under this folder:

```
%windir%\Microsoft.NET\Framework\{version}\CONFIG\web_mediumtrust.config
```

Use `Framework64` in the path instead of `Framework` if you are using a 64-bit installation of the framework.

2. Locate the `SecurityClasses` tag:

```
<SecurityClass Name="SocketPermission"
Description="System.Net.SocketPermission, System, Version=4.0.0.0,
Culture=neutral, PublicKeyToken=b77a5c561934e089"/>
```

3. Scroll down and look for the following `PermissionSet`:

```
<PermissionSet version="1" Name="ASP.Net">
```

4. Add the following inside this `PermissionSet`:

```
<IPermission class="SocketPermission" version="1" Unrestricted="true" />
```

This configuration lets you use the driver with the default Windows protocol TCP/IP without having any security issues. This approach only supports the TCP/IP protocol, so you cannot use any other type of connection.

Also, since the `MySQLClientPermissions` class is not added to the medium trust policy, you cannot use it. This configuration is the minimum required in order to work with Connector/Net without the GAC.

22.2.6. Connector/Net Connection String Options Reference

For usage information about connection strings, see [Section 22.2.5.2, "Creating a Connector/Net Connection String"](#). The first table list options that apply generally to all server configurations. The options related to systems using a connection pool are split into a separate table.

General Options

Table 22.20. Connector/Net Connection String Options - General

| Name | Default | Description |
|---|---------|---|
| <code>Allow Batch, AllowBatch</code> | true | When true, multiple SQL statements can be sent with one command execution. Note: starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Statements sent to earlier versions of MySQL should be separated by ';'. |
| <code>Allow User Variables, AllowUserVariables</code> | false | Setting this to <code>true</code> indicates that the provider expects user variables in the SQL. This option was added in Connector/Net version 5.2.2. |
| <code>Allow Zero Datetime, AllowZeroDateTime</code> | false | If set to <code>True</code> , <code>MySqlDataReader.GetValue()</code> returns a <code>MySqlDateTime</code> object for date or datetime columns that have disallowed values, such as zero datetime values, and a <code>System.DateTime</code> object for valid values. If set to <code>False</code> (the default setting) it causes a <code>System.DateTime</code> object to be returned for all valid values and an exception to be thrown for disallowed values, such as zero datetime values. |
| <code>Auto Enlist, AutoEnlist</code> | true | If <code>AutoEnlist</code> is set to <code>true</code> , which is the default, a connection opened using <code>TransactionScope</code> participates in this scope, it commits when the scope commits and rolls back if <code>TransactionScope</code> does not commit. However, this feature is considered security sensitive and therefore cannot be used in a medium trust environment. |
| <code>BlobAsUTF8ExcludePattern</code> | null | A POSIX-style regular expression that matches the names of BLOB columns that do not contain UTF-8 character data. See Section 22.2.5.16, "Character Set Considerations for Connector/Net" for usage details. |
| <code>BlobAsUTF8IncludePattern</code> | null | A POSIX-style regular expression that matches the names of BLOB columns containing UTF-8 character data. See Section 22.2.5.16, "Character Set Considerations for Connector/Net" for usage details. |
| <code>Certificate File, CertificateFile</code> | null | This option specifies the path to a certificate file in PKCS #12 format (<code>.pfx</code>). For an example of usage, see Section 22.2.4.7, "Tutorial: Using SSL with MySQL Connector/Net" . Was introduced with 6.2.1. |
| <code>Certificate Password, CertificatePassword</code> | null | Specifies a password that is used in conjunction with a certificate specified using the option <code>CertificateFile</code> . For an example of usage, see Section 22.2.4.7, "Tutorial: Using SSL with MySQL Connector/Net" . Was introduced with 6.2.1. |
| <code>Certificate Store Location, CertificateStoreLocation</code> | null | Enables you to access a certificate held in a personal store, rather than use a certificate file and password combination. For an example of usage, see Section 22.2.4.7, "Tutorial: Using SSL with MySQL Connector/Net" . Was introduced with 6.2.1. |

Connector/Net Connection String Options Reference

| Name | Default | Description |
|--|---------|---|
| <code>CertificateThumbprint</code> , <code>CertificateThumbprint</code> | null | Specifies a certificate thumbprint to ensure correct identification of a certificate contained within a personal store. For an example of usage, see Section 22.2.4.7 , “ Tutorial: Using SSL with MySQL Connector/Net ”. Was introduced with 6.2.1. |
| <code>CharSet</code> , <code>Character Set</code> , <code>CharacterSet</code> | | Specifies the character set that should be used to encode all queries sent to the server. Resultsets are still returned in the character set of the result data. |
| <code>Check Parameters</code> , <code>CheckParameters</code> | true | Indicates if stored routine parameters should be checked against the server. |
| <code>Command Interceptors</code> , <code>CommandInterceptors</code> | | The list of interceptors that can intercept SQL command operations. |
| <code>Connect Timeout</code> , <code>Connection Timeout</code> , <code>ConnectionTimeout</code> | 15 | The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error. |
| <code>Convert Zero Datetime</code> , <code>ConvertZeroDateTime</code> | false | True to have <code>MySqlDataReader.GetValue()</code> and <code>MySqlDataReader.GetDateTime()</code> return <code>DateTime.MinValue</code> for date or datetime columns that have disallowed values. |
| <code>Default Command Timeout</code> , <code>DefaultCommandTimeout</code> | 30 | Sets the default value of the command timeout to be used. This does not supercede the individual command timeout property on an individual command object. If you set the command timeout property, that will be used. This option was added in Connector/Net 5.1.4 |
| <code>Default Table Cache Age</code> , <code>DefaultTableCacheAge</code> | 60 | Specifies how long a <code>TableDirect</code> result should be cached, in seconds. For usage information about table caching, see Section 22.2.5.7 , “ Using Connector/Net with Table Caching ”. This option was added in Connector/Net 6.4. |
| <code>enableSessionExpireCallback</code> | false | When set to <code>true</code> , causes the session-expiry scanner to raise the <code>session_end</code> event before deleting the session data stored in the <code>my_aspnet_sessions</code> table, when a session times out. Enable this option to write additional application-specific cleanup code to handle the <code>session_end</code> event of the <code>global.asax</code> class, before the stored data of the session gets deleted. Within the <code>session_end</code> method, any other required cleanup can be done. This option was added in Connector/Net 6.4.5; it is not yet available in Connector/Net 6.5.x releases. |
| <code>Encrypt</code> , <code>UseSSL</code> | false | For Connector/Net 5.0.3 and later, when <code>true</code> , SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> . In versions before 5.0.3, this option had no effect. From version 6.2.1, this option is deprecated and is replaced by <code>SSL Mode</code> . The option still works if used. If this option is set to true, it is equivalent to <code>SSL Mode = Preferred</code> . |

Connector/Net Connection String Options Reference

| Name | Default | Description |
|---|-----------|--|
| Exception Interceptors , ExceptionInterceptors | | The list of interceptors that can triage thrown MySQLException exceptions. |
| Functions Return String , FunctionsReturnString | false | Causes the connector to return binary/varbinary values as strings, if they do not have a tablename in the metadata. |
| Host , Server , Data Source , DataSource , Address , Addr , Network Address | localhost | The name or network address of the instance of MySQL to which to connect. Multiple hosts can be specified separated by commas. This can be useful where multiple MySQL servers are configured for replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the database, so take care when using this option. In Unix environment with Mono, this can be a fully qualified path to a MySQL socket file. With this configuration, the Unix socket is used instead of the TCP/IP socket. Currently, only a single socket name can be given, so accessing MySQL in a replicated environment using Unix sockets is not currently supported. |
| Ignore Prepare , IgnorePrepare | true | When true, instructs the provider to ignore any calls to MySQLCommand.Prepare() . This option is provided to prevent issues with corruption of the statements when used with server-side prepared statements. If you use server-side prepare statements, set this option to false. This option was added in Connector/Net 5.0.3 and Connector/Net 1.0.9. |
| includesecurityasserts , include security asserts | false | Must be set to <code>true</code> when using the MySQLClientPermissions class in a partial trust environment, with the library installed in the GAC of the hosting environment. This requirement is new for partial-trust applications in Connector/Net 6.6.4 and higher. See Section 22.2.5.19, "Working with Partial Trust / Medium Trust" for details. |
| Initial Catalog , Database | mysql | The case-sensitive name of the database to use initially. |
| Interactive , Interactive Session , InteractiveSession | false | If set to true, the client is interactive. An interactive client is one where the server variable <code>CLIENT_INTERACTIVE</code> is set. If an interactive client is set, the <code>wait_timeout</code> variable is set to the value of <code>interactive_timeout</code> . The client will then time out after this period of inactivity. For more details, see Section 5.1.4, "Server System Variables" in the MySQL Reference Manual. |
| Integrated Security , IntegratedSecurity | no | Use Windows authentication when connecting to server. By default, it is turned off. To enable, specify a value of <code>yes</code> . (You can also use the value <code>sspi</code> as an alternative to <code>yes</code> .) For details, see Section 22.2.5.5, "Using the Windows Native Authentication Plugin" . This option was introduced in Connector/Net 6.4.4. |
| Keep Alive , Keepalive | 0 | For TCP connections, idle connection time measured in seconds, before the first keepalive packet is sent. A value of 0 indicates that keepalive is not used. |

Connector/Net Connection String Options Reference

| Name | Default | Description |
|--|---------|---|
| <code>Logging</code> | false | When true, various pieces of information is output to any configured TraceListeners. See Section 22.2.5.14, "Using the MySQL Connector/Net Trace Source Object" for further details. |
| <code>Old Guids, OldGuids</code> | false | This option was introduced in Connector/Net 6.1.1. The backend representation of a GUID type was changed from <code>BINARY(16)</code> to <code>CHAR(36)</code> . This was done to allow developers to use the server function <code>UUID() [1201]</code> to populate a GUID table - <code>UUID()</code> generates a 36-character string. Developers of older applications can add <code>'Old Guids=true'</code> to the connection string to use a GUID of data type <code>BINARY(16)</code> . |
| <code>Old Syntax, OldSyntax, Use Old Syntax, UseOldSyntax</code> | false | This option was deprecated in Connector/Net 5.2.2. All code should now be written using the '@' symbol as the parameter marker. |
| <code>Password, pwd</code> | | The password for the MySQL account being used. |
| <code>Persist Security Info, PersistSecurityInfo</code> | false | When set to <code>false</code> or <code>no</code> (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Resetting the connection string resets all connection string values, including the password. Recognized values are <code>true</code> , <code>false</code> , <code>yes</code> , and <code>no</code> . |
| <code>Pipe Name, Pipe, PipeName</code> | mysql | When set to the name of a named pipe, the <code>MySqlConnection</code> attempts to connect to MySQL on that named pipe. This setting only applies to the Windows platform. |
| <code>Port</code> | 3306 | The port MySQL is using to listen for connections. This value is ignored if Unix socket is used. |
| <code>Procedure Cache Size, ProcedureCacheSize, procedure cache, procedurecache</code> | 25 | Sets the size of the stored procedure cache. By default, Connector/Net stores the metadata (input/output data types) about the last 25 stored procedures used. To disable the stored procedure cache, set the value to zero (0). This option was added in Connector/Net 5.0.2 and Connector/Net 1.0.9. |
| <code>Protocol, Connection Protocol, ConnectionProtocol</code> | socket | Specifies the type of connection to make to the server. Values can be: <code>socket</code> or <code>tcp</code> for a socket connection, <code>pipe</code> for a named pipe connection, <code>unix</code> for a Unix socket connection, <code>memory</code> to use MySQL shared memory. |
| <code>Replication</code> | false | Indicates if this connection is to use replicated servers. |
| <code>Respect Binary Flags, RespectBinaryFlags</code> | true | Setting this option to <code>false</code> means that Connector/Net ignores a column's binary flags as set by the server. This option was added in Connector/Net version 5.1.3. |
| <code>Shared Memory Name, SharedMemoryName</code> | MYSQL | The name of the shared memory object to use for communication if the connection protocol is set to <code>memory</code> . |

| Name | Default | Description |
|--|---------|---|
| Sql Server Mode, sqlservermode | false | Allow SQL Server syntax. When set to <code>true</code> , enables Connector/Net to support square brackets around symbols instead of backticks. This enables Visual Studio wizards that bracket symbols with <code>[]</code> to work with Connector/Net. This option incurs a performance hit, so should only be used if necessary. This option was added in version 6.3.1. |
| SSL Mode, SslMode | None | <p>This option has the following values:</p> <ul style="list-style-type: none"> • None - do not use SSL. • Preferred - use SSL if the server supports it, but allow connection in all cases. • Required - Always use SSL. Deny connection if server does not support SSL. • VerifyCA - Always use SSL. Validate the CA but tolerate name mismatch. • VerifyFull - Always use SSL. Fail if the host name is not correct. <p>This option was introduced in MySQL Connector/Net 6.2.1.</p> |
| Table Cache, tablecache, tablecaching | false | Enables or disables caching of <code>TableDirect</code> commands. A value of <code>true</code> enables the cache while <code>false</code> disables it. For usage information about table caching, see Section 22.2.5.7, “Using Connector/Net with Table Caching” . This option was added in Connector/Net 6.4. |
| Treat BLOBs as UTF8, TreatBlobsAsUTF8 | false | |
| Treat Tiny As Boolean, TreatTinyAsBoolean | true | Setting this value to <code>false</code> causes <code>TINYINT(1)</code> to be treated as an <code>INT</code> . See Section 11.1.1, “Numeric Type Overview” for a further explanation of the <code>TINYINT</code> and <code>BOOL</code> data types. |
| Use Affected Rows, UseAffectedRows | false | When <code>true</code> , the connection reports changed rows instead of found rows. This option was added in Connector/Net version 5.2.6. |
| Use Procedure Bodies, UseProcedureBodies, procedure bodies | true | When set to <code>true</code> , the default value, MySQL Connector/Net expects the body of the procedure to be viewable. This enables it to determine the parameter types and order. Set the option to <code>false</code> when the user connecting to the database does not have the SELECT [697] privileges for the <code>mysql.proc</code> (stored procedures) table, or cannot view <code>INFORMATION_SCHEMA.ROUTINES</code> . In this case, MySQL Connector/Net cannot determine the types and order of the parameters, and must be alerted to this fact by setting this option to <code>false</code> . When set to <code>false</code> , MySQL Connector/Net does not rely on |

| Name | Default | Description |
|--|---------|--|
| | | this information being available when the procedure is called. Because MySQL Connector/Net will not be able to determine this information, explicitly set the types of all the parameters before the call and add the parameters to the command in the same order as they appear in the procedure definition. This option was added in MySQL Connector/Net 5.0.4 and MySQL Connector/Net 1.0.10. |
| <code>User Id</code> , <code>UserID</code> , <code>Username</code> , <code>Uid</code> , <code>User name</code> , <code>User</code> | | The MySQL login account being used. |
| <code>Compress</code> , <code>Use Compression</code> , <code>UseCompression</code> | false | <p>Setting this option to <code>true</code> enables compression of packets exchanged between the client and the server. This exchange is defined by the MySQL client/server protocol.</p> <p>Compression is used if both client and server support ZLIB compression, and the client has requested compression using this option.</p> <p>A compressed packet header is: packet length (3 bytes), packet number (1 byte), and Uncompressed Packet Length (3 bytes). The Uncompressed Packet Length is the number of bytes in the original, uncompressed packet. If this is zero, the data in this packet has not been compressed. When the compression protocol is in use, either the client or the server may compress packets. However, compression will not occur if the compressed length is greater than the original length. Thus, some packets will contain compressed data while other packets will not.</p> |
| <code>Use Usage Advisor</code> , <code>Usage Advisor</code> , <code>UseUsageAdvisor</code> | false | Logs inefficient database operations. |
| <code>Use Performance Monitor</code> , <code>UsePerformanceMonitor</code> , <code>userperfmon</code> , <code>perfmon</code> | false | Indicates that performance counters should be updated during execution. |

Connection Pooling Options

The following table lists the valid names for options related to connection pooling within the `ConnectionString`. For more information about connection pooling, see [Section 22.2.5.4, “Using Connector/Net with Connection Pooling”](#).

Table 22.21. Connector/Net Connection String Options - Connection Pooling

| Name | Default | Description |
|---|---------|--|
| <code>Cache Server Properties</code> , <code>CacheServerProperties</code> | false | Specifies whether server variable settings are updated by a <code>SHOW VARIABLES</code> command each time a pooled connection is returned. Enabling this setting speeds up connections in a connection pool environment. Your application is not informed of any changes to configuration variables made by other connections. This option was added in Connector/Net 6.3. |

| Name | Default | Description |
|---|---------|---|
| Connection Lifetime , ConnectionLifeTime | 0 | When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by Connection Lifetime . This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes pooled connections to have the maximum connection timeout. |
| Connection Reset , ConnectionReset | false | If true, the connection state is reset when it is retrieved from the pool. The default value of false avoids making an additional server round trip when obtaining a connection, but the connection state is not reset. |
| Maximum Pool Size , Max Pool Size , maximumpoolsize | 100 | The maximum number of connections allowed in the pool. |
| Minimum Pool Size , Min Pool Size , MinimumPoolSize | 0 | The minimum number of connections allowed in the pool. |
| Pooling | true | When true , the MySQLConnection object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are true , false , yes , and no . |

22.2.7. Connector/Net API Reference

This section of the manual contains a complete reference to the Connector/Net ADO.NET component, automatically generated from the embedded documentation.

22.2.7.1. [MySQL.Data.MySqlClient](#) Namespace

[Namespace hierarchy](#)

Classes

| Class | Description |
|--|---|
| BaseCommandInterceptor | Provides a means of enhancing or replacing SQL commands through the connection string rather than recompiling. |
| BaseExceptionInterceptor | Provides a means of enabling and disabling exception handling through the connection string rather than recompiling. |
| MySQLClientPermission | Derived from the .NET DBDataPermission class. For usage information, see Section 22.2.5.19 , " Working with Partial Trust / Medium Trust ". |
| MySQLCommand | |
| MySQLCommandBuilder | |
| MySQLConnection | |
| MySQLDataAdapter | |
| MySQLDataReader | Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited. |

| Class | Description |
|---|--|
| MySqlError | Collection of error codes that can be returned by the server |
| MySqlException | The exception that is thrown when MySQL returns an error. This class cannot be inherited. |
| MySqlHelper | Helper class that makes it easier to work with the provider. |
| MySqlInfoMessageEventArgs | Provides data for the InfoMessage event. This class cannot be inherited. |
| MySqlParameter | Represents a parameter to a MySqlCommand , and optionally, its mapping to DataSet columns. This class cannot be inherited. |
| MySqlParameterCollection | Represents a collection of parameters relevant to a MySqlCommand as well as their respective mappings to columns in a DataSet. This class cannot be inherited. |
| MySqlRowUpdatedEventArgs | Provides data for the RowUpdated event. This class cannot be inherited. |
| MySqlRowUpdatingEventArgs | Provides data for the RowUpdating event. This class cannot be inherited. |
| MySqlTransaction | |

Delegates

| Delegate | Description |
|--|---|
| MySqlInfoMessageEventHandler | Represents the method that will handle the InfoMessage event of a MySqlConnection . |
| MySqlRowUpdatedEventHandler | Represents the method that will handle the RowUpdated event of a MySqlDataAdapter . |
| MySqlRowUpdatingEventHandler | Represents the method that will handle the RowUpdating event of a MySqlDataAdapter . |

Enumerations

| Enumeration | Description |
|--------------------------------|--|
| MySqlDbType | Specifies MySQL-specific data type of a field, property, for use in a MySqlParameter . |
| MySqlErrorCode | |

22.2.7.1.1. [MySql.Data.MySqlClientHierarchy](#)

See Also

[MySql.Data.MySqlClient Namespace](#)

22.2.7.1.2. [BaseCommandInterceptor](#)

The [BaseCommandInterceptor](#) class has these methods that you can override:

```
public virtual bool ExecuteScalar(string sql, ref object returnValue);
```

```
public virtual bool ExecuteNonQuery(string sql, ref int returnValue);
public virtual bool ExecuteReader(string sql, CommandBehavior behavior, ref MySqlDataReader returnValue);
public virtual void Init(MySqlConnection connection);
```

If your interceptor overrides one of the `Execute...` methods, set the `returnValue` output parameter and return `true` if you handled the event, or `false` if you did not handle the event. The SQL command is processed normally only when all command interceptors return `false`.

The connection passed to the `Init` method is the connection that is attached to this interceptor.

For full usage and examples, see [Section 22.2.5.11, "Using the Connector/Net Interceptor Classes"](#).

22.2.7.1.3. BaseExceptionInterceptor

You develop an exception interceptor first by creating a subclass of the `BaseExceptionInterceptor` class. You must override the `InterceptException()` method. You can also override the `Init()` method to do some one-time initialization.

Each exception interceptor has 2 methods:

```
public abstract Exception InterceptException(Exception exception,
    MySqlConnection connection);
public virtual void Init(MySqlConnection connection);
```

The connection passed to `Init()` is the connection that is attached to this interceptor.

Each interceptor is required to override `InterceptException` and return an exception. It can return the exception it is given, or it can wrap it in a new exception. We currently do not offer the ability to suppress the exception.

For full usage and examples, see [Section 22.2.5.11, "Using the Connector/Net Interceptor Classes"](#).

22.2.7.1.4. MySqlCommand Class

For a list of all members of this type, see [MySqlCommand Members](#).

Syntax: Visual Basic

```
NotInheritable Public Class MySqlCommand_
    Inherits Component_
    Implements IDbCommand, ICloneable
```

Syntax: C#

```
public sealed class MySqlCommand : Component, IDbCommand, ICloneable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: `MySql.Data` (in `MySql.Data.dll`)

See Also

[MySqlCommand Members](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1. MySqlCommand Members[MySqlCommand overview](#)**Public Instance Constructors**

| | |
|------------------------------|---|
| MySqlCommand | Overloaded. Initializes a new instance of the MySqlCommand class. |
|------------------------------|---|

Public Instance Properties

| | |
|--------------------------------------|--|
| CommandText | |
| CommandTimeout | |
| CommandType | |
| Connection | |
| Container (inherited from Component) | Gets the IContainer that contains the Component. |
| IsPrepared | |
| Parameters | |
| Site (inherited from Component) | Gets or sets the ISite of the Component. |
| Transaction | |
| UpdatedRowSource | |

Public Instance Methods

| | |
|---|---|
| Cancel | Attempts to cancel the execution of a MySqlCommand. This operation is not supported. |
| CreateObjRef (inherited from MarshalByRefObject) | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. |
| CreateParameter | Creates a new instance of a MySqlParameter object. |
| Dispose (inherited from Component) | Releases all resources used by the Component. |
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| ExecuteNonQuery | |
| ExecuteReader | Overloaded. |
| ExecuteScalar | |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetLifetimeService (inherited from MarshalByRefObject) | Retrieves the current lifetime service object that controls the lifetime policy for this instance. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| InitializeLifetimeService (inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance. |
| Prepare | |

| | |
|-------------------------------------|--|
| ToString (inherited from Component) | Returns a String containing the name of the Component, if any. This method should not be overridden. |
|-------------------------------------|--|

Public Instance Events

| | |
|-------------------------------------|---|
| Disposed (inherited from Component) | Adds an event handler to listen to the Disposed event on the component. |
|-------------------------------------|---|

[MySqlConnection Members](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.1.3.1.1.10.1.1.1. MySqlConnection Members

[MySqlConnection overview](#)

Public Instance Properties

| | |
|--------------------------------|---|
| Connection | Gets the MySqlConnection object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid. |
| IsolationLevel | Specifies the IsolationLevel for this transaction. |

Public Instance Methods

| | |
|-------------------------------------|---|
| Commit | |
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| Rollback | |
| ToString (inherited from Object) | Returns a String that represents the current Object. |

See Also

[MySqlConnection Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.1.3.1.1.10.1.1.1.1. Connection Property

Gets the [MySqlConnection](#) object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.

Syntax: Visual Basic

```
Public ReadOnly Property Connection As MySqlConnection
```

Syntax: C#

```
public MySqlConnection Connection {get;}
```

Property Value

The [MySqlConnection](#) object associated with this transaction.

Remarks

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction created by [BeginTransaction](#).

See Also

[MySqlTransaction Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.1.3.1.1.10.1.1.1.2. IsolationLevel Property

Specifies the IsolationLevel for this transaction.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsolationLevel As IsolationLevel _  
-  
    Implements IDbTransaction.IsolationLevel
```

Syntax: C#

```
public System.Data.IsolationLevel IsolationLevel {get;}
```

Property Value

The IsolationLevel for this transaction. The default is ReadCommitted.

Implements

IDbTransaction.IsolationLevel

Remarks

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

See Also

```

Syntax: C#

```
public event MySqlInfoMessageEventHandler InfoMessage;
```

See Also

[MySQLConnection Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.1.3.1.1.16.1. [MySQLInfoMessageEventHandler](#) Delegate

Represents the method that will handle the [InfoMessage](#) event of a [MySQLConnection](#).

Syntax: Visual Basic

```
Public Delegate Sub MySqlInfoMessageEventHandler( _  
    ByVal sender As Object, _  
    ByVal args As MySqlInfoMessageEventArgs _  
)
```

Syntax: C#

```
public delegate void MySqlInfoMessageEventHandler(  
    object sender,  
    MySqlInfoMessageEventArgs args  
);
```

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.1.3.1.1.16.1.1. [MySQLInfoMessageEventArgs](#) Class

Provides data for the [InfoMessage](#) event. This class cannot be inherited.

For a list of all members of this type, see [MySQLInfoMessageEventArgs Members](#).

Syntax: Visual Basic

```
Public Class MySqlInfoMessageEventArgs_
    Inherits EventArgs
```

Syntax: C#

```
public class MySqlInfoMessageEventArgs : EventArgs
```

Thread Safety

22.2.7.1.4.1.3. [CommandTimeout](#) Property

Syntax: Visual Basic

```
NotOverridable Public Property CommandTimeout As Integer _  
_
```

```
Implements IDbCommand.CommandTimeout
```

Syntax: C#

```
public int CommandTimeout {get; set;}
```

Implements

IDbCommand.CommandTimeout

See Also

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.4. CommandType Property

Syntax: Visual Basic

```
NotOverridable Public Property CommandType As CommandType _  
_ Implements IDbCommand.CommandType
```

Syntax: C#

```
public System.Data.CommandType CommandType {get; set;}
```

Implements

IDbCommand.CommandType

See Also

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.5. Connection Property

Syntax: Visual Basic

```
Public Property Connection As MySqlConnection
```

Syntax: C#

```
public MySqlConnection Connection {get; set;}
```

See Also

[MySQLCommand Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.6. IsPrepared Property

Syntax: Visual Basic

```
Public ReadOnly Property IsPrepared As Boolean
```

Syntax: C#

```
public bool IsPrepared {get;}
```

22.2.7.1.4.1.7. Parameters Property

Syntax: Visual Basic

```
Public ReadOnly Property Parameters As MySqlParameterCollection
```

Syntax: C#

```
public MySqlParameterCollection Parameters {get;}
```

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1. [MySqlParameterCollection](#) Class

Represents a collection of parameters relevant to a [MySqlCommand](#) as well as their respective mappings to columns in a DataSet. This class cannot be inherited.

For a list of all members of this type, see [MySqlParameterCollection Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlParameterCollection_
    Inherits MarshalByRefObject_
    Implements IDataParameterCollection, IList, ICollection, IEnumerable
```

Syntax: C#

```
public sealed class MySqlParameterCollection : MarshalByRefObject, IDataParameterCollection, IList, ICollection
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySqlParameterCollection Members](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1. [MySqlParameterCollection](#) Members

[MySqlParameterCollection overview](#)

Public Instance Constructors

| | |
|--|---|
| MySqlParameterCollection Constructor | Initializes a new instance of the MySqlParameterCollection class. |
|--|---|

Public Instance Properties

| | |
|-----------------------|--|
| Count | Gets the number of MySqlParameter objects in the collection. |
|-----------------------|--|

| | |
|----------------------|---|
| Item | Overloaded. Gets the MySQLParameter with a specified attribute. In C#, this property is the indexer for the MySQLParameterCollection class. |
|----------------------|---|

Public Instance Methods

| | |
|---|---|
| Add | Overloaded. Adds the specified MySQLParameter object to the MySQLParameterCollection . |
| Clear | Removes all items from the collection. |
| Contains | Overloaded. Gets a value indicating whether a MySQLParameter exists in the collection. |
| CopyTo | Copies MySQLParameter objects from the MySQLParameterCollection to the specified array. |
| CreateObjRef (inherited from MarshalByRefObject) | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. |
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetLifetimeService (inherited from MarshalByRefObject) | Retrieves the current lifetime service object that controls the lifetime policy for this instance. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| IndexOf | Overloaded. Gets the location of a MySQLParameter in the collection. |
| InitializeLifetimeService (inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance. |
| Insert | Inserts a MySQLParameter into the collection at the specified index. |
| Remove | Removes the specified MySQLParameter from the collection. |
| RemoveAt | Overloaded. Removes the specified MySQLParameter from the collection. |
| ToString (inherited from Object) | Returns a String that represents the current Object. |

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.1. [MySQLParameterCollection](#) Constructor

Initializes a new instance of the [MySQLParameterCollection](#) class.

Syntax: Visual Basic

```
Public Sub New()
```

Syntax: C#

```
public MySqlParameterCollection();
```

See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.2. Count Property

Gets the number of [MySqlParameter](#) objects in the collection.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Count As Integer _
_
_ Implements ICollection.Count
```

Syntax: C#

```
public int Count {get;}
```

Implements

[ICollection.Count](#)

See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3. Item Property

Gets the [MySqlParameter](#) with a specified attribute. In C#, this property is the indexer for the [MySqlParameterCollection](#) class.

Overload List

Gets the [MySqlParameter](#) at the specified index.

- [public MySqlParameter this\[int\] {get; set;}](#)

Gets the [MySqlParameter](#) with the specified name.

- [public MySqlParameter this\[string\] {get; set;}](#)

See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1. [MySqlParameter](#) Class

Represents a parameter to a [MySqlCommand](#), and optionally, its mapping to [DataSet](#) columns. This class cannot be inherited.

For a list of all members of this type, see [MySqlParameter Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlParameter_
_ Inherits MarshalByRefObject_
_ Implements IDataParameter, IDbDataParameter, ICloneable
```

Syntax: C#

```
public sealed class MySqlParameter : MarshalByRefObject, IDataParameter, IDbDataParameter, ICloneable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

[MySqlParameter overview](#)

Public Instance Constructors

| | |
|--------------------------------|---|
| MySqlParameter | Overloaded. Initializes a new instance of the MySqlParameter class. |
|--------------------------------|---|

Public Instance Properties

| | |
|-------------------------------|--|
| DbType | Gets or sets the DbType of the parameter. |
| Direction | Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice. |
| IsNullable | Gets or sets a value indicating whether the parameter accepts null values. |
| IsUnsigned | |
| MySqlDbType | Gets or sets the MySqlDbType of the parameter. |
| ParameterName | Gets or sets the name of the MySqlParameter . |
| Precision | Gets or sets the maximum number of digits used to represent the Value property. |
| Scale | Gets or sets the number of decimal places to which Value is resolved. |
| Size | Gets or sets the maximum size, in bytes, of the data within the column. |
| SourceColumn | Gets or sets the name of the source column that is mapped to the DataSet and used for loading or returning the Value . |
| SourceVersion | Gets or sets the DataRowVersion to use when loading Value . |
| Value | Gets or sets the value of the parameter. |

Public Instance Methods

| | |
|---|---|
| CreateObjRef (inherited from MarshalByRefObject) | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. |
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetLifetimeService (inherited from MarshalByRefObject) | Retrieves the current lifetime service object that controls the lifetime policy for this instance. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| InitializeLifetimeService (inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance. |
| ToString | Overridden. Gets a string containing the ParameterName . |

22.2.7.1.4.1.7.1.1.3.1.1.1. [MySQLParameter](#) Constructor

Initializes a new instance of the [MySQLParameter](#) class.

Overload List

Initializes a new instance of the [MySQLParameter](#) class.

- [public MySQLParameter\(\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and the data type.

- [public MySQLParameter\(string,MySQLDbType\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#), and the size.

- [public MySQLParameter\(string,MySQLDbType,int\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a [ParameterDirection](#), the precision of the parameter, the scale of the parameter, the source column, a [DataRowVersion](#) to use, and the value of the parameter.

- [public MySQLParameter\(string,MySQLDbType,int,ParameterDirection,bool,byte,byte,string,DataRowVersion,object\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name, the [MySQLDbType](#), the size, and the source column name.

- [public MySQLParameter\(string,MySQLDbType,int,string\);](#)

Initializes a new instance of the [MySQLParameter](#) class with the parameter name and a value of the new [MySQLParameter](#).

- `public MySqlParameter(string,object);`

22.2.7.1.4.1.7.1.1.3.1.1.1.1. `MySqlParameter` Constructor ()

Initializes a new instance of the `MySqlParameter` class.

Syntax: Visual Basic

```
Overloads Public Sub New()
```

Syntax: C#

```
public MySqlParameter();
```

See Also

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameter Constructor Overload List](#)

22.2.7.1.4.1.7.1.1.3.1.1.1.2. `MySqlParameter` Constructor

Initializes a new instance of the `MySqlParameter` class with the parameter name and the data type.

Syntax: Visual Basic

```
Overloads Public Sub New( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySqlDbType _  
)
```

Syntax: C#

```
public MySqlParameter(  
    stringparameterName,  
    MySqlDbTypedbType  
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.

22.2.7.1.4.1.7.1.1.3.1.1.2.1. `MySqlDbType` Enumeration

Specifies MySQL-specific data type of a field, property, for use in a `MySqlParameter`.

Syntax: Visual Basic

```
Public Enum MySqlDbType
```

Syntax: C#

```
public enum MySqlDbType
```

Members

| Member Name | Description |
|--------------------|---|
| Newdate | Obsolete. Use Datetime or Date type. |
| Timestamp | A timestamp. The range is '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.999999'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.) |
| Time | The range is '-838:59:59.000000' to '838:59:59.000000'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.) |
| Date | The supported range is '1000-01-01' to '9999-12-31'. |
| Datetime | The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. (Fractional seconds can only be stored with a MySQL 5.6.4 or higher database server.) |
| Year | A year in 2- or 4-digit format (default is 4-digit). The allowable values are 1901 to 2155, 0000 in the 4-digit year format, and 1970-2069 if you use the 2-digit format (70-69). |
| TinyBlob | A BLOB column with a maximum length of 255 (2 ⁸ - 1) characters. |
| Blob | A BLOB column with a maximum length of 65535 (2 ¹⁶ - 1) characters. |
| MediumBlob | A BLOB column with a maximum length of 16777215 (2 ²⁴ - 1) characters. |
| LongBlob | A BLOB column with a maximum length of 4294967295 or 4G (2 ³² - 1) characters. |
| Int16 | A 16-bit signed integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535. |
| Int24 | Specifies a 24 (3 byte) signed or unsigned value. |
| Int32 | A 32-bit signed integer. |
| Int64 | A 64-bit signed integer. |
| Byte | The signed range is -128 to 127. The unsigned range is 0 to 255. |
| Float | A small (single-precision) floating-point number. Allowable values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38. |
| Double | A normal-size (double-precision) floating-point number. Allowable values are -1.7976931348623157E+308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308. |
| UByte | An 8-bit unsigned value. |

| | |
|------------|--|
| UInt16 | A 16-bit unsigned value. |
| UInt24 | A 24-bit unsigned value. |
| UInt32 | A 32-bit unsigned value. |
| UInt64 | A 64-bit unsigned value. |
| Decimal | A fixed precision and scale numeric value between $-10^{38}-1$ and $10^{38}-1$. |
| NewDecimal | New Decimal |
| Set | A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET can have a maximum of 64 members. |
| String | Obsolete. Use VarChar type. |
| VarChar | A variable-length string containing 0 to 255 characters. |
| VarString | A variable-length string containing 0 to 65535 characters. |
| Enum | An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special "" error value. An ENUM can have a maximum of 65535 distinct values. |
| Geometry | |
| Bit | Bit-field data type. |
| TinyText | A nonbinary string column supporting a maximum length of 255 ($2^8 - 1$) characters. |
| Text | A nonbinary string column supporting a maximum length of 65535 ($2^{16} - 1$) characters. |
| MediumText | A nonbinary string column supporting a maximum length of 16777215 ($2^{24} - 1$) characters. |
| LongText | A nonbinary string column supporting a maximum length of 4294967295 ($2^{32} - 1$) characters. |

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.3. [MySqlParameter](#) Constructor (String, MySqlDbType, Int32)

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the [MySqlDbType](#), and the size.

Syntax: Visual Basic

```
Overloads Public Sub New( _
```

```

    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer _
)

```

Syntax: C#

```

public MySqlParameter(
    stringparameterName,
    MySqlDbTypeDbType,
    intsize
);

```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the parameter.

See Also

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameter Constructor Overload List](#)

22.2.7.1.4.1.7.1.1.3.1.1.4. [MySqlParameter](#) Constructor

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the type of the parameter, the size of the parameter, a [ParameterDirection](#), the precision of the parameter, the scale of the parameter, the source column, a [DataRowVersion](#) to use, and the value of the parameter.

Syntax: Visual Basic

```

Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer, _
    ByVal direction As ParameterDirection, _
    ByVal isNullable As Boolean, _
    ByVal precision As Byte, _
    ByVal scale As Byte, _
    ByVal sourceColumn As String, _
    ByVal sourceVersion As DataRowVersion, _
    ByVal value As Object _
)

```

Syntax: C#

```

public MySqlParameter(
    stringparameterName,
    MySqlDbTypeDbType,
    intsize,
    ParameterDirectiondirection,
    boolisNullable,
    byteprecision,
    bytescale,
    stringsourceColumn,
    DataRowVersionsourceVersion,
    objectvalue
);

```

Parameters

- `parameterName`: The name of the parameter to map.

- **dbType**: One of the [MySqlDbType](#) values.
- **size**: The length of the parameter.
- **direction**: One of the [ParameterDirection](#) values.
- **isNullable**: true if the value of the field can be null, otherwise false.
- **precision**: The total number of digits to the left and right of the decimal point to which [Value](#) is resolved.
- **scale**: The total number of decimal places to which [Value](#) is resolved.
- **sourceColumn**: The name of the source column.
- **sourceVersion**: One of the [DataRowVersion](#) values.
- **value**: An Object that is the value of the [MySqlParameter](#).

Exceptions

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.5. [MySqlParameter](#) Constructor

Initializes a new instance of the [MySqlParameter](#) class with the parameter name, the [MySqlDbType](#), the size, and the source column name.

Syntax: Visual Basic

```
Overloads Public Sub New( _
```

```

    ByVal parameterName As String, _
    ByVal dbType As MySqlDbType, _
    ByVal size As Integer, _
    ByVal sourceColumn As String _
)

```

Syntax: C#

```

public MySqlParameter(
    stringparameterName,
    MySqlDbTypedbType,
    intsize,
    stringsourceColumn
);

```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the parameter.
- `sourceColumn`: The name of the source column.

[MySqlParameter Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameter Constructor Overload List](#)

22.2.7.1.4.1.7.1.1.3.1.1.1.6. [MySqlParameter](#) Constructor

Initializes a new instance of the [MySqlParameter](#) class with the parameter name and a value of the new [MySqlParameter](#).

Syntax: Visual Basic

```

Overloads Public Sub New( _
    ByVal parameterName As String, _
    ByVal value As Object _
)

```

Syntax: C#

```

public MySqlParameter(
    stringparameterName,
    objectvalue
);

```

Parameters

- `parameterName`: The name of the parameter to map.
- `value`: An Object that is the value of the [MySqlParameter](#).

22.2.7.1.4.1.7.1.1.3.1.1.2. DbType Property

Gets or sets the DbType of the parameter.

Syntax: Visual Basic

```
NotOverridable Public Property DbType As DbType _  
-  
    Implements IDataParameter.DbType
```

Syntax: C#

```
public System.Data.DbType DbType {get; set;}
```

Implements

IDataParameter.DbType

See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.3. Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.

Syntax: Visual Basic

```
NotOverridable Public Property Direction As ParameterDirection _  
-  
    Implements IDataParameter.Direction
```

Syntax: C#

```
public System.Data.ParameterDirection Direction {get; set;}
```

Implements

IDataParameter.Direction

See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.4. IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

Syntax: Visual Basic

```
NotOverridable Public Property IsNullable As Boolean _  
-  
    Implements IDataParameter.IsNullable
```

Syntax: C#

```
public bool IsNullable {get; set;}
```

Implements

IDataParameter.IsNullable

See Also

[MySQLParameter Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.5. IsUnsigned Property

Syntax: Visual Basic

```
Public Property IsUnsigned As Boolean
```

Syntax: C#

```
public bool IsUnsigned {get; set;}
```

See Also

[MySQLParameter Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.6. MySQLDbType Property

Gets or sets the MySQLDbType of the parameter.

Syntax: Visual Basic

```
Public Property MySQLDbType As MySQLDbType
```

Syntax: C#

```
public MySQLDbType MySQLDbType {get; set;}
```

See Also

[MySQLParameter Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.7. ParameterName Property

Gets or sets the name of the MySQLParameter.

Syntax: Visual Basic

```
NotOverridable Public Property ParameterName As String _  
_ Implements IDataParameter.ParameterName
```

Syntax: C#

```
public string ParameterName {get; set;}
```

Implements

IDataParameter.ParameterName

See Also

[MySQLParameter Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.8. Precision Property

Gets or sets the maximum number of digits used to represent the [Value](#) property.

Syntax: Visual Basic

```
NotOverridable Public Property Precision As Byte _  
-  
  Implements IDbDataParameter.Precision
```

Syntax: C#

```
public byte Precision {get; set;}
```

Implements

IDbDataParameter.Precision

See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.9. Scale Property

Gets or sets the number of decimal places to which [Value](#) is resolved.

Syntax: Visual Basic

```
NotOverridable Public Property Scale As Byte _  
-  
  Implements IDbDataParameter.Scale
```

Syntax: C#

```
public byte Scale {get; set;}
```

Implements

IDbDataParameter.Scale

See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.10. Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

Syntax: Visual Basic

```
NotOverridable Public Property Size As Integer _  
-  
  Implements IDbDataParameter.Size
```

Syntax: C#

```
public int Size {get; set;}
```

Implements

IDbDataParameter.Size

See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.11. SourceColumn Property

Gets or sets the name of the source column that is mapped to the DataSet and used for loading or returning the [Value](#).

Syntax: Visual Basic

```
NotOverridable Public Property SourceColumn As String _  
-  
    Implements IDataParameter.SourceColumn
```

Syntax: C#

```
public string SourceColumn {get; set;}
```

Implements

IDataParameter.SourceColumn

See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.12. SourceVersion Property

Gets or sets the DataRowVersion to use when loading [Value](#).

Syntax: Visual Basic

```
NotOverridable Public Property SourceVersion As DataRowVersion _  
-  
    Implements IDataParameter.SourceVersion
```

Syntax: C#

```
public System.Data.DataRowVersion SourceVersion {get; set;}
```

Implements

IDataParameter.SourceVersion

See Also

[MySQLParameter Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.1.1.13. MySQLParameter.ToString Method

Overridden. Gets a string containing the [ParameterName](#).

Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

Syntax: C#

```
public override string ToString();
```

Return Value

See Also

[MySQLParameter Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.3.2. Item Property (Int32)

Gets the [MySQLParameter](#) at the specified index.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _  
    ByVal index As Integer _  
) As MySQLParameter
```

Syntax: C#

```
public MySQLParameter this[  
    int index  
] {get; set;}
```

22.2.7.1.4.1.7.1.1.3.3. Item Property (String)

Gets the [MySQLParameter](#) with the specified name.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _  
    ByVal name As String _  
) As MySQLParameter
```

Syntax: C#

```
public MySQLParameter this[  
    string name  
] {get; set;}
```

[MySQLParameterCollection Class, MySql.Data.MySqlClient Namespace, MySQLParameterCollection.Item Overload List](#)

22.2.7.1.4.1.7.1.1.4. Add Method

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#).

Overload List

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#).

- `public MySQLParameter Add(MySQLParameter);`

Adds the specified [MySQLParameter](#) object to the [MySQLParameterCollection](#).

- `public int Add(object);`

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the parameter name and the data type.

- [public MySqlConnection Add\(string,MySqlDbType\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, and the column length.

- [public MySqlConnection Add\(string,MySqlDbType,int\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

- [public MySqlConnection Add\(string,MySqlDbType,int,string\);](#)

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) given the specified parameter name and value.

- [public MySqlConnection Add\(string,object\);](#)

See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.4.1. [MySqlParameterCollection.Add](#) Method

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#).

Syntax: Visual Basic

```
Overloads Public Function Add( _
    ByVal value As MySqlParameter _
) As MySqlParameter
```

Syntax: C#

```
public MySqlConnection Add(
    MySqlParametervalue
);
```

Parameters

- **value:** The [MySqlParameter](#) to add to the collection.

Return Value

The newly added [MySqlParameter](#) object.

See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameterCollection.Add Overload List](#)

22.2.7.1.4.1.7.1.1.4.2. [MySqlParameterCollection.Add](#) Method

Adds the specified [MySqlParameter](#) object to the [MySqlParameterCollection](#).

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Add( _
    ByVal value As Object _
) As Integer _
-
    Implements IList.Add
```

Syntax: C#

```
public int Add(  
    object value  
);
```

Parameters

- **value**: The [MySQLParameter](#) to add to the collection.

Return Value

The index of the new [MySQLParameter](#) object.

Implements

[IList.Add](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLParameterCollection.Add Overload List](#)

22.2.7.1.4.1.7.1.1.4.3. MySQLParameterCollection.Add Method

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the parameter name and the data type.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySQLDbType _  
) As MySQLParameter
```

Syntax: C#

```
public MySQLParameter Add(  
    string parameterName,  
    MySQLDbType dbType  
);
```

Parameters

- **parameterName**: The name of the parameter.
- **dbType**: One of the [MySQLDbType](#) values.

Return Value

The newly added [MySQLParameter](#) object.

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLParameterCollection.Add Overload List](#)

22.2.7.1.4.1.7.1.1.4.4. MySQLParameterCollection.Add Method

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) with the parameter name, the data type, and the column length.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySqlDbType, _  
    ByVal size As Integer _  
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(  
    stringparameterName,  
    MySqlDbTypedbType,  
    intsize  
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.
- `size`: The length of the column.

Return Value

The newly added [MySqlParameter](#) object.

See Also

[MySqlParameterCollection Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlParameterCollection.Add Overload List](#)

22.2.7.1.4.1.7.1.1.4.5. [MySqlParameterCollection.Add](#) Method

Adds a [MySqlParameter](#) to the [MySqlParameterCollection](#) with the parameter name, the data type, the column length, and the source column name.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal dbType As MySqlDbType, _  
    ByVal size As Integer, _  
    ByVal sourceColumn As String _  
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(  
    stringparameterName,  
    MySqlDbTypedbType,  
    intsize,  
    stringsourceColumn  
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the [MySqlDbType](#) values.

- `size`: The length of the column.
- `sourceColumn`: The name of the source column.

Return Value

The newly added [MySQLParameter](#) object.

22.2.7.1.4.1.7.1.1.4.6. [MySQLParameterCollection.Add](#) Method

Adds a [MySQLParameter](#) to the [MySQLParameterCollection](#) given the specified parameter name and value.

Syntax: Visual Basic

```
Overloads Public Function Add( _  
    ByVal parameterName As String, _  
    ByVal value As Object _  
) As MySQLParameter
```

Syntax: C#

```
public MySQLParameter Add(  
    stringparameterName,  
    objectvalue  
);
```

Parameters

- `parameterName`: The name of the parameter.
- `value`: The [Value](#) of the [MySQLParameter](#) to add to the collection.

Return Value

The newly added [MySQLParameter](#) object.

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLParameterCollection.Add Overload List](#)

22.2.7.1.4.1.7.1.1.5. [MySQLParameterCollection.Clear](#) Method

Removes all items from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Clear() _  
-  
    Implements IList.Clear
```

Syntax: C#

```
public void Clear();
```

Implements

IList.Clear

See Also[MySQLParameterCollection Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.6. Contains Method

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

Overload List

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

- `public bool Contains(object);`

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

- `public bool Contains(string);`

See Also[MySQLParameterCollection Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.7.1.1.6.1. [MySQLParameterCollection.Contains](#) Method

Gets a value indicating whether a [MySQLParameter](#) exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _  
    ByVal value As Object _  
) As Boolean _  
-  
    Implements IList.Contains
```

Syntax: C#

```
public bool Contains(  
    objectvalue  
);
```

Parameters

- `value`: The value of the [MySQLParameter](#) object to find.

Return Value

true if the collection contains the [MySQLParameter](#) object; otherwise, false.

Implements

IList.Contains

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),
[MySQLParameterCollection.Contains Overload List](#)

22.2.7.1.4.1.7.1.1.6.2. [MySQLParameterCollection.Contains](#) Method

Gets a value indicating whether a [MySQLParameter](#) with the specified parameter name exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _  
    ByVal name As String _  
) As Boolean _  
-  
    Implements IDataParameterCollection.Contains
```

Syntax: C#

```
public bool Contains(  
    stringname  
);
```

Parameters

- **name**: The name of the [MySQLParameter](#) object to find.

Return Value

true if the collection contains the parameter; otherwise, false.

Implements

[IDataParameterCollection.Contains](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),
[MySQLParameterCollection.Contains Overload List](#)

22.2.7.1.4.1.7.1.1.7. [MySQLParameterCollection.CopyTo](#) Method

Copies [MySQLParameter](#) objects from the [MySQLParameterCollection](#) to the specified array.

Syntax: Visual Basic

```
NotOverridable Public Sub CopyTo( _  
    ByVal array As Array, _  
    ByVal index As Integer _  
) _  
-  
    Implements ICollection.CopyTo
```

Syntax: C#

```
public void CopyTo(  
    Arrayarray,  
    intindex  
);
```

Parameters

- [array](#):
- [index \[839\]](#):

Implements

[ICollection.CopyTo](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.8. IndexOf Method

Gets the location of a [MySQLParameter](#) in the collection.

Overload List

Gets the location of a [MySQLParameter](#) in the collection.

- `public int IndexOf(object);`

Gets the location of the [MySQLParameter](#) in the collection with a specific parameter name.

- `public int IndexOf(string);`

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.8.1. `MySQLParameterCollection.IndexOf` Method

Gets the location of a [MySQLParameter](#) in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _  
    ByVal value As Object _  
) As Integer _  
—  
Implements IList.IndexOf
```

Syntax: C#

```
public int IndexOf(  
    object value  
);
```

Parameters

- `value`: The [MySQLParameter](#) object to locate.

Return Value

The zero-based location of the [MySQLParameter](#) in the collection.

Implements

[IList.IndexOf](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),
[MySQLParameterCollection.IndexOf Overload List](#)

22.2.7.1.4.1.7.1.1.8.2. [MySQLParameterCollection.IndexOf](#) Method

Gets the location of the [MySQLParameter](#) in the collection with a specific parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _  
    ByVal parameterName As String _  
) As Integer _  
-  
    Implements IDataParameterCollection.IndexOf
```

Syntax: C#

```
public int IndexOf(  
    string parameterName  
);
```

Parameters

- [parameterName](#): The name of the [MySQLParameter](#) object to retrieve.

Return Value

The zero-based location of the [MySQLParameter](#) in the collection.

Implements

[IDataParameterCollection.IndexOf](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),
[MySQLParameterCollection.IndexOf Overload List](#)

22.2.7.1.4.1.7.1.1.9. [MySQLParameterCollection.Insert](#) Method

Inserts a [MySQLParameter](#) into the collection at the specified index.

Syntax: Visual Basic

```
NotOverridable Public Sub Insert( _  
    ByVal index As Integer, _  
    ByVal value As Object _  
) _  
-  
    Implements IList.Insert
```

Syntax: C#

```
public void Insert(  
    int index,  
    object value  
);
```

Parameters

- [index \[839\]](#):
- [value](#):

Implements

[IList.Insert](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.10. [MySQLParameterCollection.Remove](#) Method

Removes the specified [MySQLParameter](#) from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Remove( _  
    ByVal value As Object _  
) _  
—  
Implements IList.Remove
```

Syntax: C#

```
public void Remove(  
    objectvalue  
);
```

Parameters

- [value](#):

Implements

[IList.Remove](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.11. [RemoveAt](#) Method

Removes the specified [MySQLParameter](#) from the collection.

Overload List

Removes the specified [MySQLParameter](#) from the collection using a specific index.

- [public void RemoveAt\(int\);](#)

Removes the specified [MySQLParameter](#) from the collection using the parameter name.

- [public void RemoveAt\(string\);](#)

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.7.1.1.11.1. [MySQLParameterCollection.RemoveAt](#) Method

Removes the specified [MySQLParameter](#) from the collection using a specific index.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _  
    ByVal index As Integer _  
) _  
-  
    Implements IList.RemoveAt
```

Syntax: C#

```
public void RemoveAt(  
    int index  
);
```

Parameters

- [index](#) [839]: The zero-based index of the parameter.

Implements

IList.RemoveAt

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),
[MySQLParameterCollection.RemoveAt Overload List](#)

22.2.7.1.4.1.7.1.1.11.2. [MySQLParameterCollection.RemoveAt](#) Method

Removes the specified [MySQLParameter](#) from the collection using the parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _  
    ByVal name As String _  
) _  
-  
    Implements IDataParameterCollection.RemoveAt
```

Syntax: C#

```
public void RemoveAt(  
    string name  
);
```

Parameters

- [name](#): The name of the [MySQLParameter](#) object to retrieve.

Implements

IDataParameterCollection.RemoveAt

See Also

[MySQLParameterCollection Class](#), [MySQL.Data.MySqlClient Namespace](#),
[MySQLParameterCollection.RemoveAt Overload List](#)

22.2.7.1.4.1.8. Transaction Property

Syntax: Visual Basic

```
Public Property Transaction As MySqlConnection
```

Syntax: C#

```
public MySqlConnection Transaction {get; set;}
```

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.9. UpdatedRowSource Property

Syntax: Visual Basic

```
NotOverridable Public Property UpdatedRowSource As UpdateRowSource _  
-  
Implements IDbCommand.UpdatedRowSource
```

Syntax: C#

```
public System.Data.UpdateRowSource UpdatedRowSource {get; set;}
```

Implements

IDbCommand.UpdatedRowSource

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.10. MySqlCommand.Cancel Method

Attempts to cancel the execution of a MySqlCommand. This operation is not supported.

Syntax: Visual Basic

```
NotOverridable Public Sub Cancel() _  
-  
Implements IDbCommand.Cancel
```

Syntax: C#

```
public void Cancel();
```

Implements

IDbCommand.Cancel

Remarks

Cancelling an executing command is currently not supported on any version of MySQL.

Exceptions

| Exception Type | Condition |
|----------------|-----------|
|----------------|-----------|

| | |
|-----------------------|----------------------------------|
| NotSupportedException | This operation is not supported. |
|-----------------------|----------------------------------|

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.11. [MySqlCommand.CreateParameter](#) Method

Creates a new instance of a [MySqlParameter](#) object.

Syntax: Visual Basic

```
Public Function CreateParameter() As MySqlParameter
```

Syntax: C#

```
public MySqlParameter CreateParameter();
```

Return Value

A [MySqlParameter](#) object.

Remarks

This method is a strongly-typed version of `CreateParameter`.

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.12. [MySqlCommand.ExecuteNonQuery](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteNonQuery() As Integer _  
—  
Implements IDbCommand.ExecuteNonQuery
```

Syntax: C#

```
public int ExecuteNonQuery();
```

Implements

`IDbCommand.ExecuteNonQuery`

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13. `ExecuteReader` Method**Overload List**

- [public MySqlDataReader ExecuteReader\(\)](#);
- [public MySqlDataReader ExecuteReader\(CommandBehavior\)](#);

See Also

[MySqlCommand Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1. [MySqlCommand.ExecuteReader](#) Method**Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader() As MySqlDataReader
```

Syntax: C#

```
public MySqlDataReader ExecuteReader();
```

See Also

[MySqlCommand Class, MySql.Data.MySqlClient Namespace, MySqlCommand.ExecuteReader Overload List](#)

22.2.7.1.4.1.13.1.1. [MySqlDataReader](#) Class

Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.

For a list of all members of this type, see [MySqlDataReader Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlDataReader_
    Inherits MarshalByRefObject_
    Implements IEnumerable, IDataReader, IDisposable, IDataRecord
```

Syntax: C#

```
public sealed class MySqlDataReader : MarshalByRefObject, IEnumerable, IDataReader, IDisposable, IDataRecord
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySqlDataReader Members, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1. [MySqlDataReader](#) Members

[MySqlDataReader overview](#)

Public Instance Properties

| | |
|------------------------|--|
| Depth | Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0. |
|------------------------|--|

| | |
|---------------------------------|--|
| FieldCount | Gets the number of columns in the current row. |
| HasRows | Gets a value indicating whether the <code>MySqlDataReader</code> contains one or more rows. |
| IsClosed | Gets a value indicating whether the data reader is closed. |
| Item | Overloaded. Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the <code>MySqlDataReader</code> class. |
| RecordsAffected | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement. |

Public Instance Methods

| | |
|--|--|
| Close | Closes the <code>MySqlDataReader</code> object. |
| CreateObjRef (inherited from <code>MarshalByRefObject</code>) | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. |
| Equals (inherited from <code>Object</code>) | Determines whether the specified <code>Object</code> is equal to the current <code>Object</code> . |
| GetBoolean | Gets the value of the specified column as a Boolean. |
| GetByte | Gets the value of the specified column as a byte. |
| GetBytes | Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset. |
| GetChar | Gets the value of the specified column as a single character. |
| GetChars | Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset. |
| GetDataTypeName | Gets the name of the source data type. |
| GetDateTime | |
| GetDecimal | |
| GetDouble | |
| GetFieldType | Gets the <code>Type</code> that is the data type of the object. |
| GetFloat | |
| GetGuid | |
| GetHashCode (inherited from <code>Object</code>) | Serves as a hash function for a particular type. <code>GetHashCode</code> is suitable for use in hashing algorithms and data structures like a hash table. |
| GetInt16 | |
| GetInt32 | |
| GetInt64 | |
| GetLifetimeService (inherited from <code>MarshalByRefObject</code>) | Retrieves the current lifetime service object that controls the lifetime policy for this instance. |

| | |
|---|--|
| GetMySqlDateTime | |
| GetName | Gets the name of the specified column. |
| GetOrdinal | Gets the column ordinal, given the name of the column. |
| GetSchemaTable | Returns a DataTable that describes the column metadata of the MySqlDataReader. |
| GetString | |
| GetTimeSpan | |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| GetUInt16 | |
| GetUInt32 | |
| GetUInt64 | |
| GetValue | Gets the value of the specified column in its native format. |
| GetValues | Gets all attribute columns in the collection for the current row. |
| InitializeLifetimeService (inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance. |
| IsDBNull | Gets a value indicating whether the column contains non-existent or missing values. |
| NextResult | Advances the data reader to the next result, when reading the results of batch SQL statements. |
| Read | Advances the MySqlDataReader to the next record. |
| ToString (inherited from Object) | Returns a String that represents the current Object. |

22.2.7.1.4.1.13.1.1.1.1. Depth Property

Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Depth As Integer _
-
    Implements IDataReader.Depth
```

Syntax: C#

```
public int Depth {get;}
```

Implements

IDataReader.Depth

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.2. FieldCount Property

Gets the number of columns in the current row.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property FieldCount As Integer _  
-  
    Implements IDataRecord.FieldCount
```

Syntax: C#

```
public int FieldCount {get;}
```

Implements

IDataRecord.FieldCount

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.3. HasRows Property

Gets a value indicating whether the MySQLDataReader contains one or more rows.

Syntax: Visual Basic

```
Public ReadOnly Property HasRows As Boolean
```

Syntax: C#

```
public bool HasRows {get;}
```

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.4. IsClosed Property

Gets a value indicating whether the data reader is closed.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsClosed As Boolean _  
-  
    Implements IDataReader.IsClosed
```

Syntax: C#

```
public bool IsClosed {get;}
```

Implements

IDataReader.IsClosed

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.5. Item Property

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the `MySqlDataReader` class.

Overload List

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the `MySqlDataReader` class.

- `public object this[int] {get;}`

Gets the value of a column in its native format. In C#, this property is the indexer for the `MySqlDataReader` class.

- `public object this[string] {get;}`

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.5.1. Item Property (Int32)

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the `MySqlDataReader` class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _  
    ByVal i As Integer _  
) _  
-  
    Implements IDataRecord.Item As Object _  
-  
    Implements IDataRecord.Item
```

Syntax: C#

```
public object this[  
    inti  
] {get;}
```

Implements

`IDataRecord.Item`

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlDataReader.Item Overload List](#)

22.2.7.1.4.1.13.1.1.1.5.2. Item Property (String)

Gets the value of a column in its native format. In C#, this property is the indexer for the `MySqlDataReader` class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _  
    ByVal name As String _  
) _  
-
```

```
Implements IDataRecord.Item As Object _  
-  
Implements IDataRecord.Item
```

Syntax: C#

```
public object this[  
stringname  
] {get;}
```

Implements

IDataRecord.Item

See Also[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLDataReader.Item Overload List](#)

22.2.7.1.4.1.13.1.1.1.6. RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property RecordsAffected As Integer _  
-  
Implements IDataReader.RecordsAffected
```

Syntax: C#

```
public int RecordsAffected {get;}
```

Implements

IDataReader.RecordsAffected

See Also[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.7. MySQLDataReader.Close Method

Closes the MySQLDataReader object.

Syntax: Visual Basic

```
NotOverridable Public Sub Close() _  
-  
Implements IDataReader.Close
```

Syntax: C#

```
public void Close();
```

Implements

IDataReader.Close

See Also[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.8. [MySqlDataReader.GetBoolean](#) Method

Gets the value of the specified column as a Boolean.

Syntax: Visual Basic

```
NotOverridable Public Function GetBoolean( _  
    ByVal i As Integer _  
) As Boolean _  
—  
    Implements IDataRecord.GetBoolean
```

Syntax: C#

```
public bool GetBoolean(  
    inti  
);
```

Parameters

- *i*:

Return Value

Implements

[IDataRecord.GetBoolean](#)

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.9. [MySqlDataReader.GetByte](#) Method

Gets the value of the specified column as a byte.

Syntax: Visual Basic

```
NotOverridable Public Function GetByte( _  
    ByVal i As Integer _  
) As Byte _  
—  
    Implements IDataRecord.GetByte
```

Syntax: C#

```
public byte GetByte(  
    inti  
);
```

Parameters

- *i*:

Return Value

Implements

[IDataRecord.GetByte](#)

See Also

[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1.1.1.10. [MySqlDataReader.GetBytes](#) Method

Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetBytes( _  
    ByVal i As Integer, _  
    ByVal dataIndex As Long, _  
    ByVal buffer As Byte(), _  
    ByVal bufferSize As Integer, _  
    ByVal length As Integer _  
    ) As Long _  
-  
    Implements IDataRecord.GetBytes
```

Syntax: C#

```
public long GetBytes(  
    inti,  
    longdataIndex,  
    byte[]buffer,  
    intbufferIndex,  
    intlength  
);
```

Parameters

- **i**: The zero-based column ordinal.
- **dataIndex**: The index within the field from which to begin the read operation.
- **buffer**: The buffer into which to read the stream of bytes.
- **bufferIndex**: The index for buffer to begin the read operation.
- **length**: The maximum length to copy into the buffer.

Return Value

The actual number of bytes read.

Implements

IDataRecord.GetBytes

See Also

[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.11. [MySqlDataReader.GetChar](#) Method

Gets the value of the specified column as a single character.

Syntax: Visual Basic

```
NotOverridable Public Function GetChar( _  
    ByVal i As Integer _
```

```
) As Char _  
-  
Implements IDataRecord.GetChar
```

Syntax: C#

```
public char GetChar(  
    inti  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.GetChar

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.12. [MySqlDataReader.GetChars](#) Method

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetChars( _  
    ByVal i As Integer, _  
    ByVal fieldOffset As Long, _  
    ByVal buffer As Char(), _  
    ByVal bufferoffset As Integer, _  
    ByVal length As Integer _  
    ) As Long _  
-  
Implements IDataRecord.GetChars
```

Syntax: C#

```
public long GetChars(  
    inti,  
    longfieldOffset,  
    char[]buffer,  
    intbufferoffset,  
    intlength  
);
```

Parameters

- `i`:
- `fieldOffset`:
- `buffer`:
- `bufferoffset`:
- `length`:

Return Value**Implements**

IDataRecord.GetChars

See Also[MySQLDataReader Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1.1.1.13. [MySQLDataReader.GetDataTypeName](#) Method

Gets the name of the source data type.

Syntax: Visual Basic

```
NotOverridable Public Function GetDataTypeName( _  
    ByVal i As Integer _  
) As String _  
-  
    Implements IDataRecord.GetDataTypeName
```

Syntax: C#

```
public string GetDataTypeName(  
    inti  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.GetDataTypeName

See Also[MySQLDataReader Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1.1.1.14. [MySQLDataReader.GetDateTime](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetDateTime( _  
    ByVal index As Integer _  
) As Date _  
-  
    Implements IDataRecord.GetDateTime
```

Syntax: C#

```
public DateTime GetDateTime(  
    int index  
);
```

Implements

IDataRecord.GetDateTime

See Also

[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.15. [MySqlDataReader.GetDecimal](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetDecimal( _  
    ByVal index As Integer _  
) As Decimal _  
-  
    Implements IDataRecord.GetDecimal
```

Syntax: C#

```
public decimal GetDecimal(  
    int index  
);
```

Implements

IDataRecord.GetDecimal

See Also

[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.16. [MySqlDataReader.GetDouble](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetDouble( _  
    ByVal index As Integer _  
) As Double _  
-  
    Implements IDataRecord.GetDouble
```

Syntax: C#

```
public double GetDouble(  
    int index  
);
```

Implements

IDataRecord.GetDouble

See Also

[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.17. [MySqlDataReader.GetFieldType](#) Method

Gets the Type that is the data type of the object.

Syntax: Visual Basic

```
NotOverridable Public Function GetFieldType( _  
    ByVal i As Integer _  
) As Type _  
-  
    Implements IDataRecord.GetFieldType
```

Syntax: C#

```
public Type GetFieldType(  
    int i  
);
```

Parameters

- `i`:

Return Value**Implements**

`IDataRecord.GetFieldType`

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.18. [MySQLDataReader.GetFloat](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetFloat( _  
    ByVal index As Integer _  
) As Single _  
—  
    Implements IDataRecord.GetFloat
```

Syntax: C#

```
public float GetFloat(  
    int index  
);
```

Implements

`IDataRecord.GetFloat`

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.19. [MySQLDataReader.GetGuid](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetGuid( _  
    ByVal index As Integer _  
) As Guid _  
—  
    Implements IDataRecord.GetGuid
```

Syntax: C#

```
public Guid GetGuid(  
    int index  
);
```

Implements

IDataRecord.GetGuid

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.20. [MySqlDataReader.GetInt16](#) Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt16( _  
    ByVal index As Integer _  
) As Short _  
-  
    Implements IDataRecord.GetInt16
```

Syntax: C#

```
public short GetInt16(  
    int index  
);
```

Implements

IDataRecord.GetInt16

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.21. [MySqlDataReader.GetInt32](#) Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt32( _  
    ByVal index As Integer _  
) As Integer _  
-  
    Implements IDataRecord.GetInt32
```

Syntax: C#

```
public int GetInt32(  
    int index  
);
```

Implements

IDataRecord.GetInt32

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.22. [MySqlDataReader.GetInt64](#) Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt64( _  
    ByVal index As Integer _  
) As Long _  
-  
    Implements IDataRecord.GetInt64
```

Syntax: C#

```
public long GetInt64(  
    int index  
);
```

Implements

IDataRecord.GetInt64

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.23. [MySQLDataReader.GetMySqlDateTime](#) Method**Syntax: Visual Basic**

```
Public Function GetMySqlDateTime( _  
    ByVal index As Integer _  
) As MySqlDateTime
```

Syntax: C#

```
public MySqlDateTime GetMySqlDateTime(  
    int index  
);
```

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.24. [MySQLDataReader.GetName](#) Method

Gets the name of the specified column.

Syntax: Visual Basic

```
NotOverridable Public Function GetName( _  
    ByVal i As Integer _  
) As String _  
—  
    Implements IDataRecord.GetName
```

Syntax: C#

```
public string GetName(  
    int i  
);
```

Parameters

- `i`:

Return Value**Implements**

IDataRecord.GetName

See Also

[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1.1.1.25. [MySqlDataReader.GetOrdinal](#) Method

Gets the column ordinal, given the name of the column.

Syntax: Visual Basic

```
NotOverridable Public Function GetOrdinal( _  
    ByVal name As String _  
) As Integer _  
-  
    Implements IDataRecord.GetOrdinal
```

Syntax: C#

```
public int GetOrdinal(  
    stringname  
);
```

Parameters

- `name`:

Return Value**Implements**

`IDataRecord.GetOrdinal`

See Also[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1.1.1.26. [MySqlDataReader.GetSchemaTable](#) Method

Returns a `DataTable` that describes the column metadata of the `MySqlDataReader`.

Syntax: Visual Basic

```
NotOverridable Public Function GetSchemaTable() As DataTable _  
-  
    Implements IDataReader.GetSchemaTable
```

Syntax: C#

```
public DataTable GetSchemaTable();
```

Return Value**Implements**

`IDataReader.GetSchemaTable`

See Also[MySqlDataReader Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1.1.1.27. [MySqlDataReader.GetString](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function GetString( _  
    ByVal index As Integer _  
) As String _  
-  
    Implements IDataRecord.GetString
```

Syntax: C#

```
public string GetString(  
    int index  
);
```

Implements

IDataRecord.GetString

See Also

[MySQLDataReader Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.28. [MySQLDataReader.GetString](#) Method**Syntax: Visual Basic**

```
Public Function GetString( _  
    ByVal index As Integer _  
) As TimeSpan
```

Syntax: C#

```
public TimeSpan GetString(  
    int index  
);
```

```
Public Function GetUInt64( _  
    ByVal index As Integer _  
) As UInt64
```

Syntax: C#

```
public ulong GetUInt64(  
    int index  
);
```

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.32. [MySqlDataReader.GetValue](#) Method

Gets the value of the specified column in its native format.

Syntax: Visual Basic

```
NotOverridable Public Function GetValue( _  
    ByVal i As Integer _  
) As Object _  
—  
    Implements IDataRecord.GetValue
```

Syntax: C#

```
public object GetValue(  
    int i  
);
```

Parameters

- `i`:

Return Value**Implements**

`IDataRecord.GetValue`

See Also

[MySqlDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.33. [MySQLDataReader](#).[GetValues](#) Method

Gets all attribute columns in the collection for the current row.

Syntax: Visual Basic

```
NotOverridable Public Function GetValues( _  
    ByVal values As Object() _  
) As Integer _  
-  
    Implements IDataRecord.GetValues
```

Syntax: C#

```
public int GetValues(  
    object[] values  
);
```

Parameters

- `values`:

Return Value

Implements

`IDataRecord.GetValues`

See Also

[MySQLDataReader Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.34. [MySQLDataReader](#).[IsDBNull](#) Method

Gets a value indicating whether the column contains non-existent or missing values.

Syntax: Visual Basic

```
NotOverridable Public Function IsDBNull( _  
    ByVal i As Integer _  
) As Boolean _  
-  
    Implements IDataRecord.IsDBNull
```

Syntax: C#

```
public bool IsDBNull(  
    inti  
);
```

Parameters

- `i`:

Return Value

Implements

`IDataRecord.IsDBNull`

See Also

[MySQLDataReader Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.4.1.13.1.1.1.35. [MySQLDataReader.NextResult](#) Method

Advances the data reader to the next result, when reading the results of batch SQL statements.

Syntax: Visual Basic

```
NotOverridable Public Function NextResult() As Boolean _  
-  
    Implements IDataReader.NextResult
```

Syntax: C#

```
public bool NextResult();
```

Return Value**Implements**

IDataReader.NextResult

See Also

[MySQLDataReader Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.1.1.1.36. [MySQLDataReader.Read](#) Method

Advances the MySQLDataReader to the next record.

Syntax: Visual Basic

```
NotOverridable Public Function Read() As Boolean _  
-  
    Implements IDataReader.Read
```

Syntax: C#

```
public bool Read();
```

Return Value**Implements**

IDataReader.Read

See Also

[MySQLDataReader Class, MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.13.2. [MySQLCommand.ExecuteReader](#) Method**Syntax: Visual Basic**

```
Overloads Public Function ExecuteReader( _  
    ByVal behavior As CommandBehavior _  
) As MySQLDataReader
```

Syntax: C#

```
public MySQLDataReader ExecuteReader(  
    CommandBehaviorbehavior  
);
```

22.2.7.1.4.1.14. [MySqlCommand.ExecuteScalar](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Function ExecuteScalar() As Object _  
    _  
    Implements IDbCommand.ExecuteScalar
```

Syntax: C#

```
public object ExecuteScalar();
```

Implements

IDbCommand.ExecuteScalar

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.4.1.15. [MySqlCommand.Prepare](#) Method**Syntax: Visual Basic**

```
NotOverridable Public Sub Prepare() _  
    _  
    Implements IDbCommand.Prepare
```

Syntax: C#

```
public void Prepare();
```

Implements

IDbCommand.Prepare

See Also

[MySqlCommand Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.5. [MySqlCommandBuilder](#) Class

For a list of all members of this type, see [MySqlCommandBuilder Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlCommandBuilder_  
    Inherits Component
```

Syntax: C#

```
public sealed class MySqlCommandBuilder : Component
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySqlCommandBuilder Members](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.5.1. MySqlCommandBuilder Members

[MySqlCommandBuilder overview](#)

Public Static (Shared) Methods

| | |
|----------------------------------|--|
| DeriveParameters | Overloaded. Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL. |
|----------------------------------|--|

Public Instance Constructors

| | |
|-------------------------------------|--|
| MySqlCommandBuilder | Overloaded. Initializes a new instance of the MySqlCommandBuilder class. |
|-------------------------------------|--|

Public Instance Properties

| | |
|--------------------------------------|--|
| Container (inherited from Component) | Gets the IContainer that contains the Component. |
| DataAdapter | |
| QuotePrefix | |
| QuoteSuffix | |
| Site (inherited from Component) | Gets or sets the ISite of the Component. |

Public Instance Methods

| | |
|--|---|
| CreateObjRef (inherited from MarshalByRefObject) | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. |
| Dispose (inherited from Component) | Releases all resources used by the Component. |
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| GetDeleteCommand | |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetInsertCommand | |
| GetLifetimeService (inherited from MarshalByRefObject) | Retrieves the current lifetime service object that controls the lifetime policy for this instance. |

| | |
|---|--|
| GetType (inherited from Object) | Gets the Type of the current instance. |
| GetUpdateCommand | |
| InitializeLifetimeService (inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance. |
| RefreshSchema | |
| ToString (inherited from Component) | Returns a String containing the name of the Component, if any. This method should not be overridden. |

Public Instance Events

| | |
|-------------------------------------|---|
| Disposed (inherited from Component) | Adds an event handler to listen to the Disposed event on the component. |
|-------------------------------------|---|

[MySQLCommandBuilder Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.5.1.1. DeriveParameters Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

Overload List

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

- [public static void DeriveParameters\(MySqlCommand\);](#)
- [public static void DeriveParameters\(MySqlCommand,bool\);](#)

See Also

[MySQLCommandBuilder Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.5.1.1.1. [MySQLCommandBuilder.DeriveParameters](#) Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySQL.

Syntax: Visual Basic

```
Overloads Public Shared Sub DeriveParameters( _
    ByVal command As MySqlCommand _
)
```

Syntax: C#

```
public static void DeriveParameters(
    MySqlCommand command
);
```

Parameters

- `command`: The MySqlCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the MySqlCommand.

Exceptions

| Exception Type | Condition |
|---------------------------|--|
| InvalidOperationException | The command text is not a valid stored procedure name. |

[MySqlDataAdapter overview](#)

Public Instance Constructors

| | |
|----------------------------------|--|
| MySqlDataAdapter | Overloaded. Initializes a new instance of the <code>MySqlDataAdapter</code> class. |
|----------------------------------|--|

Public Instance Properties

| | |
|---|--|
| <code>AcceptChangesDuringFill</code> (inherited from <code>DataAdapter</code>) | Gets or sets a value indicating whether <code>AcceptChanges</code> is called on a <code>DataRow</code> after it is added to the <code>DataTable</code> during any of the <code>Fill</code> operations. |
| <code>AcceptChangesDuringUpdate</code> (inherited from <code>DataAdapter</code>) | Gets or sets whether <code>AcceptChanges</code> is called during a <code>Update</code> . |
| <code>Container</code> (inherited from <code>Component</code>) | Gets the <code>IContainer</code> that contains the <code>Component</code> . |
| <code>ContinueUpdateOnError</code> (inherited from <code>DataAdapter</code>) | Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update. |
| DeleteCommand | Overloaded. |
| <code>FillLoadOption</code> (inherited from <code>DataAdapter</code>) | Gets or sets the <code>LoadOption</code> that determines how the adapter fills the <code>DataTable</code> from the <code>DbDataReader</code> . |
| InsertCommand | Overloaded. |
| <code>MissingMappingAction</code> (inherited from <code>DataAdapter</code>) | Determines the action to take when incoming data does not have a matching table or column. |
| <code>MissingSchemaAction</code> (inherited from <code>DataAdapter</code>) | Determines the action to take when existing <code>DataSet</code> schema does not match incoming data. |
| <code>ReturnProviderSpecificTypes</code> (inherited from <code>DataAdapter</code>) | Gets or sets whether the <code>Fill</code> method should return provider-specific values or common CLS-compliant values. |
| SelectCommand | Overloaded. |
| <code>Site</code> (inherited from <code>Component</code>) | Gets or sets the <code>ISite</code> of the <code>Component</code> . |
| <code>TableMappings</code> (inherited from <code>DataAdapter</code>) | Gets a collection that provides the master mapping between a source table and a <code>DataTable</code> . |
| <code>UpdateBatchSize</code> (inherited from <code>DbDataAdapter</code>) | Gets or sets a value that enables or disables batch processing support, and specifies the number of commands that can be executed in a batch. |
| UpdateCommand | Overloaded. |

Public Instance Methods

| | |
|---|---|
| <code>CreateObjRef</code> (inherited from <code>MarshalByRefObject</code>) | Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object. |
| <code>Dispose</code> (inherited from <code>Component</code>) | Releases all resources used by the <code>Component</code> . |
| <code>Equals</code> (inherited from <code>Object</code>) | Determines whether the specified <code>Object</code> is equal to the current <code>Object</code> . |
| <code>Fill</code> (inherited from <code>DbDataAdapter</code>) | Overloaded. Adds or refreshes rows in the <code>DataSet</code> to match those in the data source using |

| | |
|---|---|
| | the DataSetname, and creates a DataTablenamed "Table." |
| FillSchema (inherited from DbDataAdapter) | Overloaded. Configures the schema of the specified DataTablebased on the specified SchemaType. |
| GetFillParameters (inherited from DbDataAdapter) | Gets the parameters set by the user when executing an SQL SELECT statement. |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetLifetimeService (inherited from MarshalByRefObject) | Retrieves the current lifetime service object that controls the lifetime policy for this instance. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| InitializeLifetimeService (inherited from MarshalByRefObject) | Obtains a lifetime service object to control the lifetime policy for this instance. |
| ResetFillLoadOption (inherited from DataAdapter) | Resets FillLoadOptionto its default state and causes Fillto honor AcceptChangesDuringFill. |
| ShouldSerializeAcceptChangesDuringFill (inherited from DataAdapter) | Determines whether the AcceptChangesDuringFillproperty should be persisted. |
| ShouldSerializeFillLoadOption (inherited from DataAdapter) | Determines whether the FillLoadOptionproperty should be persisted. |
| ToString (inherited from Component) | Returns a String containing the name of the Component, if any. This method should not be overridden. |
| Update (inherited from DbDataAdapter) | Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet. |

Public Instance Events

| | |
|--|---|
| Disposed (inherited from Component) | Adds an event handler to listen to the Disposed event on the component. |
| FillError (inherited from DataAdapter) | Returned when an error occurs during a fill operation. |
| RowUpdated | Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires. |
| RowUpdating | Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires. |

Protected Internal Instance Properties

| | |
|--|---|
| FillCommandBehavior (inherited from DbDataAdapter) | Gets or sets the behavior of the command used to fill the data adapter. |
|--|---|

22.2.7.1.5.1.2.2.1.1.6. MySqlCommandAdapter.RowUpdated Event

Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdated As MySqlRowUpdatedEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatedEventHandler RowUpdated;
```

Event Data

The event handler receives an argument of type [MySqlRowUpdatedEventArgs](#) containing data related to this event. The following [MySqlRowUpdatedEventArgsproperties](#) provide information specific to this event.

| Property | Description |
|-------------------------|---|
| Command | Gets or sets the MySqlCommand executed when Update is called. |
| Errors | Gets any errors generated by the .NET Framework data provider when the Commandwas executed. |
| RecordsAffected | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement. |
| Row | Gets the DataRow sent through an Update. |
| RowCount | Gets the number of rows processed in a batch of updated records. |

| | |
|---------------|--|
| StatementType | Gets the type of SQL statement executed. |
| Status | Gets the UpdateStatus of the Commandproperty. |
| TableMapping | Gets the DataTableMappingsent through an Update. |

[MySqlRowUpdatedEventArgs](#) overview

Public Instance Constructors

| | |
|--|---|
| MySqlRowUpdatedEventArgs Constructor | Initializes a new instance of the MySqlRowUpdatedEventArgs class. |
|--|---|

Public Instance Properties

| | |
|---|--|
| Command | Overloaded. Gets or sets the MySqlCommand executed when Update is called. |
| Errors (inherited from RowUpdatedEventArgs) | Gets any errors generated by the .NET Framework data provider when the Command was executed. |
| RecordsAffected (inherited from RowUpdatedEventArgs) | Gets the number of rows changed, inserted, or deleted by execution of the SQL statement. |
| Row (inherited from RowUpdatedEventArgs) | Gets the DataRow sent through an Update . |
| RowCount (inherited from RowUpdatedEventArgs) | Gets the number of rows processed in a batch of updated records. |
| StatementType (inherited from RowUpdatedEventArgs) | Gets the type of SQL statement executed. |
| Status (inherited from RowUpdatedEventArgs) | Gets the UpdateStatus of the Command property. |
| TableMapping (inherited from RowUpdatedEventArgs) | Gets the DataTableMapping sent through an Update . |

Public Instance Methods

| | |
|--|---|
| CopyToRows (inherited from RowUpdatedEventArgs) | Overloaded. Copies references to the modified rows into the provided array. |
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object . |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| ToString (inherited from Object) | Returns a String that represents the current Object . |

[MySqlRowUpdatedEventArgs](#) Class, [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.5.1.2.2.1.1.6.1.1.1.1. [MySqlRowUpdatedEventArgs](#) Constructor

Initializes a new instance of the [MySqlRowUpdatedEventArgs](#) class.

Syntax: Visual Basic

```
Public Sub New( _
    ByVal row As DataRow, _
    ByVal command As IDbCommand, _
    ByVal statementType As StatementType, _
    ByVal tableMapping As DataTableMapping _
)
```

Syntax: C#

```
public MySqlRowUpdatedEventArgs(
    DataRow row,
    IDbCommand command,
    StatementType statementType,
    DataTableMapping tableMapping
);
```

Parameters

- **row**: The DataRow sent through an Update.
- **command**: The IDbCommand executed when Update is called.
- **statementType**: One of the StatementType values that specifies the type of query executed.
- **tableMapping**: The DataTableMapping sent through an Update.

[MySqlRowUpdatedEventArgs Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.5.1.2.2.1.1.7. [MySqlDataAdapter.RowUpdating](#) Event

Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdating As MySqlRowUpdatingEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatingEventHandler RowUpdating;
```

Event Data

The event handler receives an argument of type [MySqlRowUpdatingEventArgs](#) containing data related to this event. The following [MySqlRowUpdatingEventArgsproperties](#) provide information specific to this event.

| Property | Description |
|-------------------------|---|
| Command | Gets or sets the MySqlCommand to execute when performing the Update. |
| Errors | Gets any errors generated by the .NET Framework data provider when the Command executes. |
| Row | Gets the DataRow that will be sent to the server as part of an insert, update, or delete operation. |
| StatementType | Gets the type of SQL statement to execute. |
| Status | Gets or sets the UpdateStatus of the Commandproperty. |
| TableMapping | Gets the DataTableMapping to send through the Update. |

22.2.7.1.5.1.2.2.1.1.7.1.1.1.1. [MySqlRowUpdatingEventArgs](#) Constructor

Initializes a new instance of the [MySqlRowUpdatingEventArgs](#) class.

Syntax: Visual Basic

```
Public Sub New( _
    ByVal row As DataRow, _
    ByVal command As IDbCommand, _
    ByVal statementType As StatementType, _
    ByVal tableMapping As DataTableMapping _
)
```

Syntax: C#

```
public MySqlRowUpdatingEventArgs(
    DataRow row,
    IDbCommand command,
    StatementType statementType,
    DataTableMapping tableMapping
);
```

Parameters

- [row](#): The [DataRow](#) to update.
- [command](#): The [IDbCommand](#) to execute during update.
- [statementType](#): One of the [StatementType](#) values that specifies the type of query executed.
- [tableMapping](#): The [DataTableMapping](#) sent through an update.

22.2.7.1.6. MySqlConnectionException Class

The exception that is thrown when MySQL returns an error. This class cannot be inherited.

For a list of all members of this type, see [MySqlConnectionException Members](#).

Syntax: Visual Basic

```
NotInheritable Public Class MySqlConnectionException_
    Inherits SystemException
```

Syntax: C#

```
public sealed class MySqlConnectionException : SystemException
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySQL.Data.MySqlClient](#)

Assembly: MySQL.Data (in MySQL.Data.dll)

See Also

[MySqlConnectionException Members](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.6.1. MySqlConnectionException Members

[MySqlConnectionException overview](#)

Public Instance Properties

| | |
|---|---|
| Data (inherited from Exception) | Gets a collection of key/value pairs that provide additional, user-defined information about the exception. |
| HelpLink (inherited from Exception) | Gets or sets a link to the help file associated with this exception. |
| InnerException (inherited from Exception) | Gets the ExceptionInstance that caused the current exception. |
| Message (inherited from Exception) | Gets a message that describes the current exception. |
| Number | Gets a number that identifies the type of error. This number corresponds to the error numbers given in Section C.3, "Server Error Codes and Messages" . |

| | |
|---------------------------------------|--|
| Source (inherited from Exception) | Gets or sets the name of the application or the object that causes the error. |
| StackTrace (inherited from Exception) | Gets a string representation of the frames on the call stack at the time the current exception was thrown. |
| TargetSite (inherited from Exception) | Gets the method that throws the current exception. |

Public Instance Methods

| | |
|---|---|
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| GetBaseException (inherited from Exception) | When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetObjectData (inherited from Exception) | When overridden in a derived class, sets the SerializationInfo with information about the exception. |
| GetType (inherited from Exception) | Gets the runtime type of the current instance. |
| ToString (inherited from Exception) | Creates and returns a string representation of the current exception. |

22.2.7.1.6.1.1. Number Property

Gets a number that identifies the type of error.

Syntax: Visual Basic

```
Public ReadOnly Property Number As Integer
```

Syntax: C#

```
public int Number {get;}
```

See Also

[MySqlException Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.7. MySqlHelper Class

Helper class that makes it easier to work with the provider.

For a list of all members of this type, see [MySqlHelper Members](#) .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlHelper
```

Syntax: C#

```
public sealed class MySqlHelper
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: [MySql.Data.MySqlClient](#)

Assembly: MySql.Data (in MySql.Data.dll)

See Also

[MySqlHelper Members](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.7.1. [MySqlHelper](#) Members

[MySqlHelper overview](#)

Public Static (Shared) Methods

| | |
|---------------------------------|--|
| ExecuteDataRow | Executes a single SQL statement and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method. |
| ExecuteDataset | Overloaded. Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method. |
| ExecuteNonQuery | Overloaded. Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes. |
| ExecuteReader | Overloaded. Executes a single command against a MySQL database. |
| ExecuteScalar | Overloaded. Execute a single command against a MySQL database. |
| UpdateDataSet | Updates the given table with data from the given DataSet |

Public Instance Methods

| | |
|-------------------------------------|---|
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| ToString (inherited from Object) | Returns a String that represents the current Object. |

See Also

[MySQLHelper Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.7.1.1. [MySQLHelper.ExecuteDataRow](#) Method

Executes a single SQL statement and returns the first row of the resultset. A new [MySQLConnection](#) object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Public Shared Function ExecuteDataRow( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray parms As MySqlParameter() _  
) As DataRow
```

Syntax: C#

```
public static DataRow ExecuteDataRow(  
    string connectionString,  
    string commandText,  
    params MySqlParameter[] parms  
);
```

Parameters

- [connectionString](#): Settings to be used for the connection
- [commandText](#): Command to execute
- [parms](#): Parameters to use for the command

Return Value

[DataRow](#) containing the first row of the resultset

See Also[MySQLHelper Class, MySql.Data.MySqlClient Namespace](#)22.2.7.1.7.1.2. [ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a [DataSet](#). The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

Overload List

Executes a single SQL statement and returns the resultset in a [DataSet](#). The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

- [public static DataSet ExecuteDataset\(MySqlConnection,string\);](#)

Executes a single SQL statement and returns the resultset in a [DataSet](#). The state of the [MySQLConnection](#) object remains unchanged after execution of this method.

- [public static DataSet ExecuteDataset\(MySqlConnection,string,params MySqlParameter\[\]\);](#)

Executes a single SQL statement and returns the resultset in a [DataSet](#). A new [MySQLConnection](#) object is created, opened, and closed during this method.

- [public static DataSet ExecuteDataset\(string,string\);](#)

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- [public static DataSet ExecuteDataset\(string,string,params MySqlParameter\[\]\);](#)

See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.7.1.2.1. [MySqlHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(  
    MySqlConnectionconnection,  
    stringcommandText  
);
```

Parameters

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command to execute

Return Value

DataSetcontaining the resultset

22.2.7.1.7.1.2.2. [MySqlHelper.ExecuteDataset](#) Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the [MySqlConnection](#) object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(  
    MySqlConnectionconnection,  
    stringcommandText,  
    params MySqlParameter[]commandParameters  
);
```

Parameters

- `connection`: [MySQLConnection](#) object to use
- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

Return Value

DataSet containing the resultset

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteDataset Overload List](#)

22.2.7.1.7.1.2.3. MySQLHelper.ExecuteDataset Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySQLConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connectionString As String, _  
    ByVal commandText As String _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(  
    string connectionString,  
    string commandText  
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute

Return Value

DataSet containing the resultset

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteDataset Overload List](#)

22.2.7.1.7.1.2.4. MySQLHelper.ExecuteDataset Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySQLConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
    string connectionString,
    string commandText,
    params MySqlParameter[] commandParameters
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

Return Value

DataSet containing the resultset

See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteDataset Overload List](#)

22.2.7.1.7.1.3. ExecuteNonQuery Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

Overload List

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

- [public static int ExecuteNonQuery\(MySqlConnection, string, params MySqlParameter\[\]\)](#);

Executes a single command against a MySQL database. A new [MySqlConnection](#) is created using the [ConnectionString](#) given.

- [public static int ExecuteNonQuery\(string, string, params MySqlParameter\[\]\)](#);

See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.7.1.3.1. [MySqlHelper.ExecuteNonQuery](#) Method

Executes a single command against a MySQL database. The [MySqlConnection](#) is assumed to be open when the method is called and remains open after the method completes.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _
    ByVal connection As MySqlConnection, _
    ByVal commandText As String, _
    ParamArray commandParameters As MySqlParameter() _
) As Integer
```

Syntax: C#

```
public static int ExecuteNonQuery(
```

```

MySQLConnection connection,
string commandText,
    params MySqlParameter[] commandParameters
);

```

Parameters

- `connection`: [MySQLConnection](#) object to use
- `commandText`: SQL statement to be executed
- `commandParameters`: Array of [MySqlParameter](#) objects to use with the command.

Return Value

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteNonQuery Overload List](#)

22.2.7.1.7.1.3.2. [MySQLHelper.ExecuteNonQuery](#) Method

Executes a single command against a MySQL database. A new [MySQLConnection](#) is created using the [ConnectionString](#) given.

Syntax: Visual Basic

```

Overloads Public Shared Function ExecuteNonQuery( _
    ByVal connectionString As String, _
    ByVal commandText As String, _
    ParamArray parms As MySqlParameter() _
) As Integer

```

Syntax: C#

```

public static int ExecuteNonQuery(
    string connectionString,
    string commandText,
    params MySqlParameter[] parms
);

```

Parameters

- `connectionString`: [ConnectionString](#) to use
- `commandText`: SQL statement to be executed
- `parms`: Array of [MySqlParameter](#) objects to use with the command.

Return Value

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteNonQuery Overload List](#)

22.2.7.1.7.1.4. [ExecuteReader](#) Method

Executes a single command against a MySQL database.

Overload List

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string\);](#)

Executes a single command against a MySQL database.

- [public static MySqlDataReader ExecuteReader\(string,string,params MySqlParameter\[\]\);](#)

See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#)

22.2.7.1.7.1.4.1. [MySqlHelper.ExecuteReader](#) Method

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _  
    ByVal connectionString As String, _  
    ByVal commandText As String _  
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(  
stringconnectionString,  
stringcommandText  
);
```

Parameters

- [connectionString](#): Settings to use for this command
- [commandText](#): Command text to use

Return Value

[MySqlDataReader](#) object ready to read the results of the command

See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteReader Overload List](#)

22.2.7.1.7.1.4.2. [MySqlHelper.ExecuteReader](#) Method

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(  
stringconnectionString,  
stringcommandText,  
params MySqlParameter[]commandParameters  
);
```

Parameters

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use
- `commandParameters`: Array of [MySQLParameter](#) objects to use with the command

Return Value

[MySQLDataReader](#) object ready to read the results of the command

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteReader Overload List](#)

22.2.7.1.7.1.5. ExecuteScalar Method

Execute a single command against a MySQL database.

Overload List

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(MySqlConnection,string,params MySQLParameter\[\]\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string\);](#)

Execute a single command against a MySQL database.

- [public static object ExecuteScalar\(string,string,params MySQLParameter\[\]\);](#)

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#)

22.2.7.1.7.1.5.1. [MySQLHelper.ExecuteScalar](#) Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String _  
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(  
    MySqlConnectionconnection,  
    stringcommandText  
);
```

Parameters

- `connection`: [MySqlConnection](#) object to use

- `commandText`: Command text to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteScalar Overload List](#)

22.2.7.1.7.1.5.2. `MySQLHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _  
    ByVal connection As MySqlConnection, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(  
    MySqlConnection connection,  
    string commandText,  
    params MySqlParameter[] commandParameters  
);
```

Parameters

- `connection`: [MySqlConnection](#) object to use
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

[MySQLHelper Class](#), [MySQL.Data.MySqlClient Namespace](#), [MySQLHelper.ExecuteScalar Overload List](#)

22.2.7.1.7.1.5.3. `MySQLHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _  
    ByVal connectionString As String, _  
    ByVal commandText As String _  
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(  
    string connectionString,  
    string commandText
```

```
);
```

Parameters

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteScalar Overload List](#)

22.2.7.1.7.1.5.4. `MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ParamArray commandParameters As MySqlParameter() _  
    ) As Object
```

Syntax: C#

```
public static object ExecuteScalar(  
    string connectionString,  
    string commandText,  
    params MySqlParameter[] commandParameters  
);
```

Parameters

- `connectionString`: Settings to use for the command
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

[MySqlHelper Class](#), [MySql.Data.MySqlClient Namespace](#), [MySqlHelper.ExecuteScalar Overload List](#)

22.2.7.1.7.1.6. `MySqlHelper.UpdateDataSet` Method

Updates the given table with data from the given DataSet

Syntax: Visual Basic

```
Public Shared Sub UpdateDataSet( _  
    ByVal connectionString As String, _  
    ByVal commandText As String, _  
    ByVal ds As DataSet, _
```

```
    ByVal tablename As String _
)
```

Syntax: C#

```
public static void UpdateDataSet(
    stringconnectionString,
    stringcommandText,
    DataSetds,
    stringtablename
);
```

Parameters

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update
- `ds`: DataSetcontaining the new data to use in the update
- `tablename`: Tablename in the data set to update

Public Instance Constructors

| | |
|--|------|
| MySqlConnectionException Constructor | Ctor |
|--|------|

Public Instance Properties

| | |
|---|---|
| Data (inherited from Exception) | Gets a collection of key/value pairs that provide additional, user-defined information about the exception. |
| HelpLink (inherited from Exception) | Gets or sets a link to the help file associated with this exception. |
| InnerException (inherited from Exception) | Gets the ExceptionInstance that caused the current exception. |
| Message (inherited from Exception) | Gets a message that describes the current exception. |
| Source (inherited from Exception) | Gets or sets the name of the application or the object that causes the error. |
| StackTrace (inherited from Exception) | Gets a string representation of the frames on the call stack at the time the current exception was thrown. |
| TargetSite (inherited from Exception) | Gets the method that throws the current exception. |

Public Instance Methods

| | |
|---|---|
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object. |
| GetBaseException (inherited from Exception) | When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions. |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetObjectData (inherited from Exception) | When overridden in a derived class, sets the SerializationInfo with information about the exception. |
| GetType (inherited from Exception) | Gets the runtime type of the current instance. |
| ToString (inherited from Exception) | Creates and returns a string representation of the current exception. |

Protected Instance Properties

| | |
|------------------------------------|--|
| HResult (inherited from Exception) | Gets or sets HRESULT , a coded numeric value that is assigned to a specific exception. |
|------------------------------------|--|

Protected Instance Methods

| | |
|---|--|
| Finalize (inherited from Object) | Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection. |
| MemberwiseClone (inherited from Object) | Creates a shallow copy of the current Object. |

Public Static (Shared) Type Conversions

| | |
|---|--|
| Explicit MySQLDateTime to DateTime Conversion | |
|---|--|

Public Instance Properties

| | |
|---------------------|--|
| Day | Returns the day portion of this datetime |
|---------------------|--|

| | |
|--|---|
| Hour | Returns the hour portion of this datetime |
| IsNull (inherited from MySqlValue) | |
| IsValidDateTime | Indicates if this object contains a value that can be represented as a DateTime |
| Minute | Returns the minute portion of this datetime |
| Month | Returns the month portion of this datetime |
| Second | Returns the second portion of this datetime |
| Millisecond | Returns the millisecond portion of this datetime |
| ValueAsObject (inherited from MySqlValue) | Returns the value of this field as an object |
| Year | Returns the year portion of this datetime |

Public Instance Methods

| | |
|--|---|
| Equals (inherited from Object) | Determines whether the specified Object is equal to the current Object . |
| GetDateTime | Returns this value as a DateTime |
| GetHashCode (inherited from Object) | Serves as a hash function for a particular type. GetHashCode is suitable for use in hashing algorithms and data structures like a hash table. |
| GetType (inherited from Object) | Gets the Type of the current instance. |
| ToString | Returns a MySQL-specific string representation of this value |

Protected Instance Fields

| | |
|--|---|
| classType (inherited from MySqlValue) | The system type represented by this value |
| dbType (inherited from MySqlValue) | The generic dbtype of this value |
| isNull (inherited from MySqlValue) | Is this value null |
| mysqlDbType (inherited from MySqlValue) | The specific MySQL db type |
| mysqlTypeName (inherited from MySqlValue) | The MySQL-specific typename of this value |
| objectValue (inherited from MySqlValue) | |

Protected Instance Methods

| | |
|--|--|
| Finalize (inherited from Object) | Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection. |
| MemberwiseClone (inherited from Object) | Creates a shallow copy of the current Object . |

22.2.8. Connector/Net Support

The developers of Connector/Net greatly value the input of our users in the software development process. If you find Connector/Net lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in [Section 1.7, "How to Report Bugs or Problems"](#).

22.2.8.1. Connector/Net Community Support

- Community support for Connector/Net can be found through the forums at <http://forums.mysql.com>.
- Community support for Connector/Net can also be found through the mailing lists at <http://lists.mysql.com>.
- Paid support is available from Oracle. Additional information is available at <http://dev.mysql.com/support/>.

22.2.8.2. How to Report Connector/Net Problems or Bugs

If you encounter difficulties or problems with Connector/Net, contact the Connector/Net community, as explained in [Section 22.2.8.1, "Connector/Net Community Support"](#).

First try to execute the same SQL statements and commands from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in Connector/Net or MySQL.

If reporting a problem, ideally include the following information with the email:

- Operating system and version.
- Connector/Net version.
- MySQL server version.
- Copies of error messages or other unexpected output.
- Simple reproducible sample.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through <http://bugs.mysql.com/>.

22.2.9. Connector/Net FAQ

Questions

- [23.2.9.1: \[2902\]](#) How do I obtain the value of an auto-incremented column?

Questions and Answers

23.2.9.1: How do I obtain the value of an auto-incremented column?

When using `CommandBuilder`, setting `ReturnGeneratedIdentifiers` property to `true` no longer works, as `CommandBuilder` does not add `last_insert_id()` by default.

`CommandBuilder` hooks up to the `DataAdapter.RowUpdating` event handler, which means it will get called for every row. It examines the command object and, if it is the same referenced object, it essentially rebuilds the object, thereby destroying your command text changes.

One approach to solving this problem is to clone the command object so you have a different actual reference:

```
dataAdapter.InsertCommand = cb.GetInsertCommand().Clone()
```

This will work, but since the `CommandBuilder` is still connected to the `DataAdapter`, the `RowUpdating` event will still fire and performance will be hit. To stop that, once all your commands have been added you need to disconnect the `CommandBuilder` from the `DataAdapter`:

```
cb.DataAdapter = null;
```

The last requirement is to make sure the `id` that is returned by `last_insert_id()` has the correct name. For example:

```
SELECT last_insert_id() AS id
```

A complete working example is shown here:

```
using System;  
using System.Collections.Generic;  
using System.Linq;
```

```
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace GetAutoIncId
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=*****";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT * FROM TestTable";

                MySqlDataAdapter da = new MySqlDataAdapter(sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(da);

                MySqlCommand cmd = new MySqlCommand();
                cmd.Connection = conn;
                cmd.CommandText = sql;
                // use Cloned object to avoid .NET rebuilding the object, and
                // thereby throwing away our command text additions.
                MySqlCommand insertCmd = cb.GetInsertCommand().Clone();
                insertCmd.CommandText = insertCmd.CommandText + ";SELECT last_insert_id() AS id";
                insertCmd.UpdatedRowSource = UpdateRowSource.FirstReturnedRecord;
                da.InsertCommand = insertCmd;
                cb.DataAdapter = null; // Unhook RowUpdating event handler

                DataTable dt = new DataTable();
                da.Fill(dt);

                DataRow row = dt.NewRow();
                row["name"] = "Joe Smith";

                dt.Rows.Add(row);
                da.Update(dt);

                System.Console.WriteLine("ID after update: " + row["id"]);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

22.3. MySQL Connector/J

This section explains how to configure and develop Java applications with MySQL Connector/J, the JDBC driver that is integrated with MySQL.

For release notes detailing the changes in each release of Connector/J, see [MySQL Connector/J Release Notes](#).

22.3.1. Overview of MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language through a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC Type 4 driver. Different versions are available that are compatible with the JDBC 3.0 and JDBC 4.0 specifications. The Type 4 designation means that the driver is a pure Java implementation of the MySQL protocol and does not rely on the MySQL client libraries.

For large-scale programs that use common design patterns of data access, consider using one of the popular persistence frameworks such as [Hibernate](#), [Spring's JDBC templates](#) or [Ibatis SQL Maps](#) to reduce the amount of JDBC code for you to debug, tune, secure, and maintain.

Key Topics

- For help with connection strings, connection options, and setting up your connection through JDBC, see [Section 22.3.5.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#).

22.3.2. Connector/J Versions

There are currently four versions of MySQL Connector/J available:

- Connector/J 5.1 is the Type 4 pure Java JDBC driver, which conforms to the JDBC 3.0 and JDBC 4.0 specifications. It provides compatibility with all the functionality of MySQL, including 4.1, 5.0, 5.1, 5.4 and 5.5. Connector/J 5.1 provides ease of development features, including auto-registration with the Driver Manager, standardized validity checks, categorized SQLExceptions, support for the JDBC-4.0 XML processing, per connection client information, [NCHAR](#), [NVARCHAR](#) and [NCLOB](#) types. This release also includes all bug fixes up to and including Connector/J 5.0.6.
- Connector/J 5.0 provides support for all the functionality offered by Connector/J 3.1 and includes distributed transaction (XA) support.
- Connector/J 3.1 was designed for connectivity to MySQL 4.1 and MySQL 5.0 servers and provides support for all the functionality in MySQL 5.0 except distributed transaction (XA) support.
- Connector/J 3.0 provides core functionality and was designed for connectivity to MySQL 3.x or MySQL 4.1 servers, although it provides basic compatibility with later versions of MySQL. Connector/J 3.0 does not support server-side prepared statements, and does not support any of the features in versions of MySQL later than 4.1.

The following table summarizes the Connector/J versions available, along with the details of JDBC driver type, what version of the JDBC API it supports, what versions of MySQL Server it works with, and whether it is currently supported or not:

Table 22.22. Summary of Connector/J Versions

| Connector/J version | Driver Type | JDBC version | MySQL Server version | Status |
|---------------------|-------------|--------------|-------------------------|---------------------|
| 5.1 | 4 | 3.0, 4.0 | 4.1, 5.0, 5.1, 5.4, 5.5 | Recommended version |
| 5.0 | 4 | 3.0 | 4.1, 5.0 | Released version |
| 3.1 | 4 | 3.0 | 4.1, 5.0 | Obsolete |

| Connector/J version | Driver Type | JDBC version | MySQL Server version | Status |
|---------------------|-------------|--------------|----------------------|----------|
| 3.0 | 4 | 3.0 | 3.x, 4.1 | Obsolete |

The current recommended version for Connector/J is 5.1. This guide covers all four connector versions, with specific notes given where a setting applies to a specific option.

22.3.2.1. Java Versions Supported

The following table summarizes what version of Java RTE is required to use Connector/J with Java applications, and what version of JDK is required to build Connector/J source code:

Table 22.23. Summary of Java Versions Required by Connector/J

| Connector/J version | Java RTE required | JDK required (to build source code) |
|---------------------|-----------------------------------|-------------------------------------|
| 5.1 | 1.5.x, 1.6.x | 1.6.x and 1.5.x |
| 5.0 | 1.3.x, 1.4.x, 1.5.x, 1.6.x | 1.4.2, 1.5.x, 1.6.x |
| 3.1 | 1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x | 1.4.2, 1.5.x, 1.6.x |
| 3.0 | 1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x | 1.4.2, 1.5.x, 1.6.x |

If you are building Connector/J from source code using the source distribution (see [Section 22.3.3.4, “Installing from the Development Source Tree”](#)), you must use JDK 1.4.2 or newer to compile the Connector package. For Connector/J 5.1, you must have both JDK-1.6.x and JDK-1.5.x installed to be able to build the source code.

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on a Java runtime older than 1.4 unless the class verifier is turned off (by setting the `-Xverify:none` option to the Java runtime). This is because the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use `savepoint` functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x.

22.3.3. Connector/J Installation

You can install the Connector/J package using either the binary or source distribution. The binary distribution provides the easiest method for installation; the source distribution lets you customize your installation further. With either solution, you manually add the Connector/J location to your Java `CLASSPATH`.

If you are upgrading from a previous version, read the upgrade information in [Section 22.3.3.3, “Upgrading from an Older Version”](#) before continuing.

Connector/J is also available as part of the Maven project. For more information, and to download the Connector/J JAR files, see the [Maven repository](#).

22.3.3.1. Installing Connector/J from a Binary Distribution

For the easiest method of installation, use the binary distribution of the Connector/J package. The binary distribution is available either as a tar/gzip or zip file. Extract it to a suitable location, then optionally

make the information about the package available by changing your `CLASSPATH` (see [Section 22.3.3.2, “Installing the Driver and Configuring the `CLASSPATH`”](#)).

MySQL Connector/J is distributed as a `.zip` or `.tar.gz` archive containing the sources, the class files, and the JAR archive named `mysql-connector-java-version-bin.jar`.

Starting with Connector/J 3.1.9, the `.class` files that constitute the JAR files are only included as part of the driver JAR file.

Starting with Connector/J 3.1.8, the archive also includes a debug build of the driver in a file named `mysql-connector-java-version-bin-g.jar`. Do not use the debug build of the driver unless instructed to do so when reporting a problem or a bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

Use the appropriate graphical or command-line utility to extract the distribution (for example, WinZip for the `.zip` archive, and `tar` for the `.tar.gz` archive). Because there are potentially long file names in the distribution, we use the GNU tar archive format. Use GNU tar (or an application that understands the GNU tar archive format) to unpack the `.tar.gz` variant of the distribution.

22.3.3.2. Installing the Driver and Configuring the `CLASSPATH`

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connector-java-version-bin.jar` in your classpath, either by adding the full path to it to your `CLASSPATH` environment variable, or by directly specifying it with the command line switch `-cp` when starting the JVM.

To use the driver with the JDBC `DriverManager`, use `com.mysql.jdbc.Driver` as the class that implements `java.sql.Driver`.

You can set the `CLASSPATH` environment variable under UNIX, Linux or Mac OS X either locally for a user within their `.profile`, `.login` or other login file. You can also set it globally by editing the global `/etc/profile` file.

For example, add the Connector/J driver to your `CLASSPATH` using one of the following forms, depending on your command shell:

```
# Bourne-compatible shell (sh, ksh, bash, zsh):
shell> export CLASSPATH=/path/mysql-connector-java-ver-bin.jar:$CLASSPATH

# C shell (csh, tcsh):
shell> setenv CLASSPATH /path/mysql-connector-java-ver-bin.jar:$CLASSPATH
```

Within Windows 2000, Windows XP, Windows Server 2003 and Windows Vista, you set the environment variable through the System Control Panel.

To use MySQL Connector/J with an application server such as GlassFish, Tomcat or JBoss, read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the `CLASSPATH` environment variable. For configuration examples for some J2EE application servers, see [Section 22.3.7, “Connection Pooling with Connector/J”](#), [Section 22.3.8, “Load Balancing with Connector/J”](#), and [Section 22.3.9, “Failover with Connector/J”](#). However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's `.jar` file in the `WEB-INF/lib` subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MysqlDataSource` or `MysqlConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented using the `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MysqlDataSource` classes support the following parameters (through standard set mutators):

- `user`
- `password`
- `serverName` (see the previous section about fail-over hosts)
- `databaseName`
- `port`

22.3.3.3. Upgrading from an Older Version

This section has information for users who are upgrading from one version of Connector/J to another, or to a new version of the MySQL server that supports a more recent level of JDBC. A newer version of Connector/J might include changes to support new features, improve existing functionality, or comply with new standards.

22.3.3.3.1. Upgrading to MySQL Connector/J 5.1.x

- In Connector/J 5.0.x and earlier, the alias for a table in a `SELECT` statement is returned when accessing the result set metadata using `ResultSetMetaData.getColumnName()`. This behavior however is not JDBC compliant, and in Connector/J 5.1 this behavior was changed so that the original table name, rather than the alias, is returned.

The JDBC-compliant behavior is designed to let API users reconstruct the DML statement based on the metadata within `ResultSet` and `ResultSetMetaData`.

You can get the alias for a column in a result set by calling `ResultSetMetaData.getColumnLabel()`. To use the old noncompliant behavior with `ResultSetMetaData.getColumnName()`, use the `useOldAliasMetadataBehavior` option and set the value to `true`.

In Connector/J 5.0.x, the default value of `useOldAliasMetadataBehavior` was `true`, but in Connector/J 5.1 this was changed to a default value of `false`.

22.3.3.3.2. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in `latin1` tables on the server.

Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, add the following property to your connection URL:

```
useOldUTF8Behavior=true
```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your

application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

22.3.3.3.3. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, `SQLState` codes returned in error messages by the server and various performance enhancements that can be enabled or disabled using configuration properties.

- **Unicode Character Sets:** See the next section, as well as [Section 10.1, “Character Set Support”](#), for information on this MySQL feature. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.
- **Server-side Prepared Statements:** Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

Starting with version 3.1.7, the driver scans SQL you are preparing using all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing `emulateUnsupportedPstmts=false` in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the connection property `useServerPrepStmts=false`.

- **Datetimes** with all-zero components (`0000-00-00 . . .`): These values cannot be represented reliably in Java. Connector/J 3.0.x always converted them to `NULL` when being read from a `ResultSet`.

Connector/J 3.1 throws an exception by default when these values are encountered, as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the `zeroDateTimeBehavior` configuration property. The permissible values are:

- `exception` (the default), which throws an `SQLException` with an `SQLState` of `S1009`.
- `convertToNull`, which returns `NULL` instead of the date.
- `round`, which rounds the date to the nearest closest value which is `0001-01-01`.

Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior using `noDatetimeStringSync=true` (the default value is `false`) so that you can retrieve the unaltered all-zero value as a `String`. Note that this also precludes using any time zone conversions, therefore the driver will not allow you to enable `noDatetimeStringSync` and `useTimezone` at the same time.

- **New SQLState Codes:** Connector/J 3.1 uses SQL:1999 `SQLState` codes returned by the MySQL server (if supported), which are different from the legacy X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return `SQLStates` as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the configuration property `useSqlStateCodes=false`.
- **`ResultSet.getString()`:** Calling `ResultSet.getString()` on a `BLOB` column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the `BLOB`. `BLOB`

values have no character set, so they cannot be converted to `java.lang.Strings` without data loss or corruption.

To store strings in MySQL with LOB behavior, use one of the `TEXT` types, which the driver will treat as a `java.sql.Clob`.

- **Debug builds:** Starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-version-bin-g.jar` is shipped alongside the normal binary jar file that is named `mysql-connector-java-version-bin.jar`.

Starting with Connector/J 3.1.9, we do not ship the `.class` files unbundled, they are only available in the JAR archives that ship with the driver.

Do not use the debug build of the driver unless instructed to do so when reporting a problem or bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

22.3.3.4. Installing from the Development Source Tree

Caution

Read this section only if you are interested in helping us test our new code. To just get MySQL Connector/J up and running on your system, use a standard binary release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- A Bazaar client, to check out the sources from our Launchpad repository (available from <http://bazaar-vcs.org/>).
- Apache Ant version 1.7 or newer (available from <http://ant.apache.org/>).
- JDK 1.4.2 or later. Although MySQL Connector/J can be used with older JDKs, compiling it from source requires at least JDK 1.4.2. To build Connector/J 5.1 requires JDK 1.6.x *and* an older JDK such as JDK 1.5.x; point your `JAVA_HOME` environment variable at the older installation.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. Check out the latest code from the branch that you want with one of the following commands.

The source code repository for MySQL Connector/J is located on Launchpad at <https://code.launchpad.net/connectorj>. To check out the latest development branch, use:

```
shell> bzo branch lp:connectorji
```

This creates a `connectorj` subdirectory in the current directory that contains the latest sources for the requested branch.

To check out the latest 5.1 code, use:

```
shell> bzo branch lp:connectorj/5.1
```

This creates a `5.1` subdirectory in the current directory containing the latest 5.1 code.

2. To build Connector/J 5.1, make sure that you have both JDK 1.6.x installed and an older JDK such as JDK 1.5.x. This is because Connector/J supports both JDBC 3.0 (which was prior to JDK 1.6.x) and JDBC 4.0. Set your `JAVA_HOME` environment variable to the path of the older JDK installation.

3. Change your current working directory to either the `connectorj` or `5.1` directory, depending on which branch you intend to build.
4. To build Connector/J 5.1, edit the `build.xml` to reflect the location of your JDK 1.6.x installation. The lines to change are:

```
<property name="com.mysql.jdbc.java6.javac" value="C:\jvms\jdk1.6.0\bin\javac.exe" />
<property name="com.mysql.jdbc.java6.rtjar" value="C:\jvms\jdk1.6.0\jre\lib\rt.jar" />
```

Alternatively, you can set the value of these property names through the Ant `-D` option.

5. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

```
shell> ant dist
```

This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

```
shell> ant -projecthelp
```

6. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-version`.

Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL, by following the instructions in [Section 22.3.3.2, "Installing the Driver and Configuring the CLASSPATH"](#).

A package containing both the binary and source code for Connector/J 5.1 can also be found at the following location: [Connector/J 5.1 Download](#)

22.3.4. Connector/J Examples

Examples of using Connector/J are located throughout this document. This section provides a summary and links to these examples.

- [Example 22.1, "Connector/J: Obtaining a connection from the DriverManager"](#)
- [Example 22.2, "Connector/J: Using java.sql.Statement to execute a SELECT query"](#)
- [Example 22.3, "Connector/J: Calling Stored Procedures"](#)
- [Example 22.4, "Connector/J: Using Connection.prepareStatement\(\)"](#)
- [Example 22.5, "Connector/J: Registering output parameters"](#)
- [Example 22.6, "Connector/J: Setting CallableStatement input parameters"](#)
- [Example 22.7, "Connector/J: Retrieving results and output parameter values"](#)
- [Example 22.8, "Connector/J: Retrieving AUTO_INCREMENT column values using Statement.getGeneratedKeys\(\)"](#)
- [Example 22.9, "Connector/J: Retrieving AUTO_INCREMENT column values using SELECT LAST_INSERT_ID\(\)"](#)
- [Example 22.10, "Connector/J: Retrieving AUTO_INCREMENT column values in Updatable ResultSets"](#)

- [Example 22.11, “Connector/J: Using a connection pool with a J2EE application server”](#)
- [Example 22.12, “Connector/J: Example of transaction with retry logic”](#)

22.3.5. Connector/J (JDBC) Reference

This section of the manual contains reference material for MySQL Connector/J.

22.3.5.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements `java.sql.Driver` in MySQL Connector/J is `com.mysql.jdbc.Driver`. The `org.gjt.mm.mysql.Driver` class name is also usable for backward compatibility with MM.MySQL, the predecessor of Connector/J. Use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

JDBC URL Format

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([,]) being optional:

```
jdbc:mysql://[host][,failoverhost...][:port]/[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

If the host name is not specified, it defaults to `127.0.0.1`. If the port is not specified, it defaults to `3306`, the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

Here is a sample connection URL:

```
jdbc:mysql://localhost:3306/sakila?profileSQL=true
```

IPv6 Connections

For IPv6 connections, use this alternative syntax to specify hosts in the URL, `address=(key=value)`. Supported keys are:

- `(protocol=tcp)`, or `(protocol=pipe)` for named pipes on Windows.
- `(path=path_to_pipe)` for named pipes.
- `(host=hostname)` for TCP connections.
- `(port=port_number)` for TCP connections.

For example:

```
jdbc:mysql://address=(protocol=tcp)(host=localhost)(port=3306)(user=test)/db
```

Any other parameters are treated as host-specific properties that follow the conventions of the JDBC URL properties. This now allows per-host overrides of any configuration property for multi-host connections (that is, when using failover, load balancing, or replication). Limit the overrides to user, password, network timeouts and statement and metadata cache sizes; the results of other per-host overrides are not defined.

Initial Database for Connection

If the database is not specified, the connection is made with no default database. In this case, either call the `setCatalog()` method on the Connection instance, or fully specify table names using the database

name (that is, `SELECT dbname.tablename.colname FROM dbname.tablename...`) in your SQL. Opening a connection without specifying the database to use is generally only useful when building tools that work with multiple databases, such as GUI database managers.

Note

Always use the `Connection.setCatalog()` method to specify the desired database in JDBC applications, rather than the `USE database` statement.

Failover Support

MySQL Connector/J has failover support. This enables the driver to fail over to any number of slave hosts and still perform read-only queries. Failover only happens when the connection is in an `autoCommit(true)` state, because failover cannot happen reliably when a `transaction` is in progress. Most application servers and connection pools set `autoCommit` to `true` at the end of every transaction/connection use.

The failover functionality has the following behavior:

- If the URL property `autoReconnect` is `false`: Failover only happens at connection initialization, and fallback occurs when the driver determines that the first host has become available again.
- If the URL property `autoReconnect` is `true`: Failover happens when the driver determines that the connection has failed (checked before every query), and falls back to the first host when it determines that the host has become available again (after `queriesBeforeRetryMaster` queries have been issued).

In either case, whenever you are connected to a “failed-over” server, the connection is set to read-only state, so queries that attempt to modify data will throw exceptions (the query will **never** be processed by the MySQL server).

Setting Configuration Properties

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a `DataSource` object or for a `Connection` object.

Configuration properties can be set in one of the following ways:

- Using the `set*()` methods on MySQL implementations of `java.sql.DataSource` (which is the preferred method when using implementations of `java.sql.DataSource`):
 - `com.mysql.jdbc.jdbc2.optional.MysqlDataSource`
 - `com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource`
- As a key/value pair in the `java.util.Properties` instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of the `javax.sql.DataSource.setURL()` method.

Note

If the mechanism you use to configure a JDBC URL is XML-based, use the XML character literal `&` to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following tables.

Connection/Authentication.

| Property Name | Definition | Default Value | Since Version |
|--|---|---|---------------|
| <code>user</code> | The user to connect as | | all versions |
| <code>password</code> | The password to use when connecting | | all versions |
| <code>socketFactory</code> | The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor. | com.mysql.jdbc.StandardSocketFactory | 3.0.3 |
| <code>connectTimeout</code> | Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'. | 0 | 3.0.1 |
| <code>socketTimeout</code> | Timeout on network socket operations (0, the default means no timeout). | 0 | 3.0.1 |
| <code>connectionLifecycleInterceptors</code> | A comma-delimited list of classes that implement "com.mysql.jdbc.ConnectionLifecycleInterceptor" that should notified of connection lifecycle events (creation, destruction, commit, rollback, setCatalog and setAutoCommit) and potentially alter the execution of these commands. ConnectionLifecycleInterceptors are "stackable", more than one interceptor may be specified via the configuration property as a comma-delimited list, with the interceptors executed in order from left to right. | | 5.1.4 |
| <code>useConfigs</code> | Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation. | | 3.1.5 |
| <code>authenticationPlugins</code> | Comma-delimited list of classes that implement com.mysql.jdbc.AuthenticationPlugin and which will be used for authentication unless disabled by "disabledAuthenticationPlugins" property. | | 5.1.19 |
| <code>defaultAuthenticationPlugin</code> | Name of a class implementing com.mysql.jdbc.AuthenticationPlugin which will be used as the default authentication plugin (see below). It is an error to use a class which is not listed in "authenticationPlugins" nor it is one of the built-in plugins. It is an error to set as default a plugin which was disabled with "disabledAuthenticationPlugins" property. It is an error to set this value to null or the empty string (i.e. there must be at least a valid default authentication | com.mysql.jdbc.authentication.DefaultAuthenticationPlugin | 5.1.19 |

| | | | |
|--|---|--------------------|--------|
| | plugin specified for the connection, meeting all constraints listed above). | | |
| <code>disabledAuthenticationPlugins</code> | Comma-delimited list of classes implementing <code>com.mysql.jdbc.AuthenticationPlugin</code> or mechanisms, i.e. "mysql_native_password". The authentication plugins or mechanisms listed will not be used for authentication which will fail if it requires one of them. It is an error to disable the default authentication plugin (either the one named by "defaultAuthenticationPlugin" property or the hard-coded one if "defaultAuthenticationPlugin" property is not set). | | 5.1.19 |
| <code>interactiveClient</code> | Set the <code>CLIENT_INTERACTIVE</code> flag, which tells MySQL to timeout connections based on <code>INTERACTIVE_TIMEOUT</code> instead of <code>WAIT_TIMEOUT</code> | <code>false</code> | 3.1.0 |
| <code>localSocketAddress</code> | Hostname or IP address given to explicitly configure the interface that the driver will bind the client side of the TCP/IP connection to when connecting. | | 5.0.5 |
| <code>propertiesTransform</code> | An implementation of <code>com.mysql.jdbc.ConnectionPropertiesTransform</code> that the driver will use to modify URL properties passed to the driver before attempting a connection | | 3.1.4 |
| <code>useCompression</code> | Use zlib compression when communicating with the server (true/false)? Defaults to 'false'. | <code>false</code> | 3.0.17 |

Networking.

| Property Name | Definition | Default Value | Since Version |
|-------------------------------|---|-------------------|---------------|
| <code>maxAllowedPacket</code> | Maximum allowed packet size to send to server. If not set, the value of system variable 'max_allowed_packet' will be used to initialize this upon connecting. This value will not take effect if set larger than the value of 'max_allowed_packet'. | <code>-1</code> | 5.1.8 |
| <code>tcpKeepAlive</code> | If connecting using TCP/IP, should the driver set <code>SO_KEEPALIVE</code> ? | <code>true</code> | 5.0.7 |
| <code>tcpNoDelay</code> | If connecting using TCP/IP, should the driver set <code>SO_TCP_NODELAY</code> (disabling the Nagle Algorithm)? | <code>true</code> | 5.0.7 |
| <code>tcpRcvBuf</code> | If connecting using TCP/IP, should the driver set <code>SO_RCV_BUF</code> to the given value? The default value of '0', means use the platform default value for this property) | <code>0</code> | 5.0.7 |
| <code>tcpSndBuf</code> | If connecting using TCP/IP, should the driver set <code>SO_SND_BUF</code> to the given value? The default value of '0', means use the platform default value for this property) | <code>0</code> | 5.0.7 |
| <code>tcpTrafficClass</code> | If connecting using TCP/IP, should the driver set traffic class or type-of-service fields ?See the | <code>0</code> | 5.0.7 |

| | | | |
|--|--|--|--|
| | documentation for <code>java.net.Socket.setTrafficClass()</code> for more information. | | |
|--|--|--|--|

High Availability and Clustering.

| Property Name | Definition | Default Value | Since Version |
|---------------------------------------|---|--------------------|---------------|
| <code>autoReconnect</code> | Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications don't handle <code>SQLExceptions</code> properly, and is only designed to be used when you are unable to configure your application to handle <code>SQLExceptions</code> resulting from dead and stale connections properly. Alternatively, as a last option, investigate setting the MySQL server variable "wait_timeout" to a high value, rather than the default of 8 hours. | <code>false</code> | 1.1 |
| <code>autoReconnectForPools</code> | Use a reconnection strategy appropriate for connection pools (defaults to 'false') | <code>false</code> | 3.1.3 |
| <code>failOverReadOnly</code> | When failing over in <code>autoReconnect</code> mode, should the connection be set to 'read-only'? | <code>true</code> | 3.0.12 |
| <code>maxReconnects</code> | Maximum number of reconnects to attempt if <code>autoReconnect</code> is true, default is '3'. | 3 | 1.1 |
| <code>reconnectAtTxEnd</code> | If <code>autoReconnect</code> is set to true, should the driver attempt reconnections at the end of every transaction? | <code>false</code> | 3.0.10 |
| <code>retriesAllDown</code> | When using loadbalancing, the number of times the driver should cycle through available hosts, attempting to connect. Between cycles, the driver will pause for 250ms if no servers are available. | 120 | 5.1.6 |
| <code>initialTimeout</code> | If <code>autoReconnect</code> is enabled, the initial time to wait between re-connect attempts (in seconds, defaults to '2'). | 2 | 1.1 |
| <code>roundRobinLoadBalance</code> | When <code>autoReconnect</code> is enabled, and <code>failoverReadOnly</code> is false, should we pick hosts to connect to on a round-robin basis? | <code>false</code> | 3.1.2 |
| <code>queriesBeforeRetryMaster</code> | Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50. | 50 | 3.0.2 |
| <code>secondsBeforeRetryMaster</code> | How long should the driver wait, when failed over, before attempting | 30 | 3.0.2 |

Connector/J (JDBC) Reference

| | | | |
|--|---|---|-------|
| <code>selfDestructOnPingMaxOpenConnections</code> | If set to a non-zero value, the driver will report close the connection and report failure when <code>Connection.ping()</code> or <code>Connection.isValid(int)</code> is called if the connection's count of commands sent to the server exceeds this value. | 0 | 5.1.6 |
| <code>selfDestructOnPingSecondOpenConnections</code> | If set to a non-zero value, the driver will report close the connection and report failure when <code>Connection.ping()</code> or <code>Connection.isValid(int)</code> is called if the connection's lifetime exceeds this value. | 0 | 5.1.6 |
| <code>resourceId</code> | A globally unique name that identifies the resource that this datasource or connection is connected to, used for <code>XAResource.isSameRM()</code> when the driver can't determine this value based on hostnames used in the URL | | 5.0.1 |

Security.

| Property Name | Definition | Default Value | Since Version |
|--|---|---------------|---------------|
| <code>allowMultiQueries</code> | Allow the use of ';' to delimit multiple queries during one statement (true/false), defaults to 'false', and does not affect the <code>addBatch()</code> and <code>executeBatch()</code> methods, which instead rely on <code>rewriteBatchStatements</code> . | false | 3.1.1 |
| <code>useSSL</code> | Use SSL when communicating with the server (true/false), defaults to 'false' | false | 3.0.2 |
| <code>requireSSL</code> | Require SSL connection if <code>useSSL=true</code> ? (defaults to 'false'). | false | 3.1.0 |
| <code>verifyServerCertificate</code> | If "useSSL" is set to "true", should the driver verify the server's certificate? When using this feature, the keystore parameters should be specified by the "clientCertificateKeyStore*" properties, rather than system properties. | true | 5.1.6 |
| <code>clientCertificateKeyStoreURL</code> | URL to the client certificate KeyStore (if not specified, use defaults) | | 5.1.0 |
| <code>clientCertificateKeyStoreType</code> | KeyStore type for client certificates (NULL or empty means use the default, which is "JKS". Standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM. | JKS | 5.1.0 |
| <code>clientCertificateKeyStorePassword</code> | Password for the client certificates KeyStore | | 5.1.0 |
| <code>trustCertificateKeyStoreURL</code> | URL to the trusted root certificate KeyStore (if not specified, use defaults) | | 5.1.0 |
| <code>trustCertificateKeyStoreType</code> | KeyStore type for trusted root certificates (NULL or empty means use the default, which is "JKS". Standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM. | JKS | 5.1.0 |

| | | | |
|---|--|--------------------|-------|
| <code>trustCertificateKeyStorePassword</code> | Password for the trusted root certificates KeyStore | | 5.1.0 |
| <code>allowLoadLocalInfile</code> | Should the driver allow use of 'LOAD DATA LOCAL INFILE...' (defaults to 'true'). | <code>true</code> | 3.0.3 |
| <code>allowUrlInLocalInfile</code> | Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements? | <code>false</code> | 3.1.4 |
| <code>paranoid</code> | Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false') | <code>false</code> | 3.0.1 |
| <code>passwordCharacterEncoding</code> | What character encoding is used for passwords? Leaving this set to the default value (null), uses the platform character set, which works for ISO8859_1 (i.e. "latin1") passwords. For passwords in other character encodings, the encoding will have to be specified with this property, as it's not possible for the driver to auto-detect this. | | 5.1.7 |

Performance Extensions.

| Property Name | Definition | Default Value | Since Version |
|---------------------------------------|--|------------------------------------|---------------|
| <code>callableStmtCacheSize</code> | If 'cacheCallableStmts' is enabled, how many callable statements should be cached? | 100 | 3.1.2 |
| <code>metadataCacheSize</code> | The number of queries to cache ResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50) | 50 | 3.1.1 |
| <code>useLocalSessionState</code> | Should the driver refer to the internal values of autocommit and transaction isolation that are set by <code>Connection.setAutoCommit()</code> and <code>Connection.setTransactionIsolation()</code> and transaction state as maintained by the protocol, rather than querying the database or blindly sending commands to the database for <code>commit()</code> or <code>rollback()</code> method calls? | <code>false</code> | 3.1.7 |
| <code>useLocalTransactionState</code> | Should the driver use the in-transaction state provided by the MySQL protocol to determine if a <code>commit()</code> or <code>rollback()</code> should actually be sent to the database? | <code>false</code> | 5.1.7 |
| <code>prepStmtCacheSize</code> | If prepared statement caching is enabled, how many prepared statements should be cached? | 25 | 3.0.10 |
| <code>prepStmtCacheSqlLimit</code> | If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for? | 256 | 3.0.10 |
| <code>parseInfoCacheFactory</code> | Name of a class implementing <code>com.mysql.jdbc.CacheAdapterFactory</code> , which will be used to create caches for the parsed representation of client-side prepared statements. | <code>com.mysql.jdbc.PerCon</code> | 5.1.16 |
| <code>alwaysSendSetIsolation</code> | Should the driver always communicate with the database when <code>Connection.setTransactionIsolation()</code> is | <code>true</code> | 3.1.7 |

| | | | |
|---------------------------------------|---|----------------------|--------|
| | called? If set to false, the driver will only communicate with the database when the requested transaction isolation is different than the whichever is newer, the last value that was set via <code>Connection.setTransactionIsolation()</code> , or the value that was read from the server when the connection was established. Note that <code>useLocalSessionState=true</code> will force the same behavior as <code>alwaysSendSetIsolation=false</code> , regardless of how <code>alwaysSendSetIsolation</code> is set. | | |
| <code>maintainTimeStats</code> | Should the driver maintain various internal timers to enable idle time calculations as well as more verbose error messages when the connection to the server fails? Setting this property to false removes at least two calls to <code>System.currentTimeMillis()</code> per query. | <code>true</code> | 3.1.9 |
| <code>useCursorFetch</code> | If connected to MySQL > 5.0.2, and <code>setFetchSize() > 0</code> on a statement, should that statement use cursor-based fetching to retrieve rows? | <code>false</code> | 5.0.0 |
| <code>blobSendChunkSize</code> | Chunk to use when sending BLOB/CLOBs via <code>ServerPreparedStatement</code> s | <code>1048576</code> | 3.1.9 |
| <code>cacheCallableStmts</code> | Should the driver cache the parsing stage of <code>CallableStatements</code> | <code>false</code> | 3.1.2 |
| <code>cachePrepStmts</code> | Should the driver cache the parsing stage of <code>PreparedStatement</code> s of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves? | <code>false</code> | 3.0.10 |
| <code>cacheResultSetMetadata</code> | Should the driver cache <code>ResultSetMetaData</code> for <code>Statements</code> and <code>PreparedStatement</code> s? (Req. JDK-1.4+, true/false, default 'false') | <code>false</code> | 3.1.1 |
| <code>cacheServerConfiguration</code> | Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis? | <code>false</code> | 3.1.5 |
| <code>defaultFetchSize</code> | The driver will call <code>setFetchSize(n)</code> with this value on all newly-created <code>Statements</code> | <code>0</code> | 3.1.9 |
| <code>dontTrackOpenResources</code> | The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling <code>close()</code> on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications. | <code>false</code> | 3.1.7 |
| <code>dynamicCalendars</code> | Should the driver retrieve the default calendar when required, or cache it per connection/session? | <code>false</code> | 3.1.5 |
| <code>elideSetAutoCommits</code> | If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by <code>Connection.setAutoCommit(boolean)</code> ? | <code>false</code> | 3.1.3 |

| | | | |
|--|--|---------------------|--------|
| <code>enableQueryTimeouts</code> | When enabled, query timeouts set via <code>Statement.setQueryTimeout()</code> use a shared <code>java.util.Timer</code> instance for scheduling. Even if the timeout doesn't expire before the query is processed, there will be memory used by the <code>TimerTask</code> for the given timeout which won't be reclaimed until the time the timeout would have expired if it hadn't been cancelled by the driver. High-load environments might want to consider disabling this functionality. | <code>true</code> | 5.0.6 |
| <code>holdResultsOpenOverStatementClose</code> | Should the driver close result sets on <code>Statement.close()</code> as required by the JDBC specification? | <code>false</code> | 3.1.7 |
| <code>largeRowSizeThreshold</code> | What size result set row should the JDBC driver consider "large", and thus use a more memory-efficient way of representing the row internally? | 2048 | 5.1.1 |
| <code>loadBalanceStrategy</code> | If using a load-balanced connection to connect to SQL nodes in a MySQL Cluster/NDB configuration (by using the URL prefix <code>"jdbc:mysql:loadbalance://"</code>), which load balancing algorithm should the driver use: (1) "random" - the driver will pick a random host for each request. This tends to work better than round-robin, as the randomness will somewhat account for spreading loads where requests vary in response time, while round-robin can sometimes lead to overloaded nodes if there are variations in response times across the workload. (2) "bestResponseTime" - the driver will route the request to the host that had the best response time for the previous transaction. | <code>random</code> | 5.0.6 |
| <code>locatorFetchBufferSize</code> | If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for <code>getBinaryInputStream()</code> ? | 1048576 | 3.2.1 |
| <code>rewriteBatchedStatements</code> | Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when <code>executeBatch()</code> is called? Notice that this has the potential for SQL injection if using plain <code>java.sql.Statements</code> and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite option, and that if you don't specify stream lengths when using <code>PreparedStatement.set*Stream()</code> , the driver won't be able to determine the optimum number of parameters per batch and you might receive an error from the driver that the resultant packet is too large. <code>Statement.getGeneratedKeys()</code> for these rewritten statements only works when the entire batch includes INSERT statements. | <code>false</code> | 3.1.13 |

| | | | |
|--------------------------------------|---|--------------------|-------|
| <code>useDirectRowUnpack</code> | Use newer result set row unpacking code that skips a copy from network buffers to a MySQL packet instance and instead reads directly into the result set row data buffers. | <code>true</code> | 5.1.1 |
| <code>useDynamicCharsetInfo</code> | Should the driver use a per-connection cache of character set information queried from the server when necessary, or use a built-in static mapping that is more efficient, but isn't aware of custom character sets or character sets implemented after the release of the JDBC driver? | <code>true</code> | 5.0.6 |
| <code>useFastDateParsing</code> | Use internal String->Date/Time/Timestamp conversion routines to avoid excessive object creation? | <code>true</code> | 5.0.5 |
| <code>useFastIntParsing</code> | Use internal String->Integer conversion routines to avoid excessive object creation? | <code>true</code> | 3.1.4 |
| <code>useJvmCharsetConverters</code> | Always use the character encoding routines built into the JVM, rather than using lookup tables for single-byte character sets? | <code>false</code> | 5.0.1 |
| <code>useReadAheadInput</code> | Use newer, optimized non-blocking, buffered input stream when reading from the server? | <code>true</code> | 3.1.5 |

Debugging/Profiling.

| Property Name | Definition | Default Value | Since Version |
|--|---|--|---------------|
| <code>logger</code> | The name of a class that implements "com.mysql.jdbc.log.Log" that will be used to log messages to. (default is "com.mysql.jdbc.log.StandardLogger", which logs to STDERR) | <code>com.mysql.jdbc.log.StandardLogger</code> | 3.1.1 |
| <code>gatherPerfMetrics</code> | Should the driver gather performance metrics, and report them via the configured logger every 'reportMetricsIntervalMillis' milliseconds? | <code>false</code> | 3.1.2 |
| <code>profileSQL</code> | Trace queries and their execution/fetch times to the configured logger (true/false) defaults to 'false' | <code>false</code> | 3.1.0 |
| <code>profileSql</code> | Deprecated, use 'profileSQL' instead. Trace queries and their execution/fetch times on STDERR (true/false) defaults to 'false' | | 2.0.14 |
| <code>reportMetricsIntervalMillis</code> | If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)? | <code>30000</code> | 3.1.2 |
| <code>maxQuerySizeToLog</code> | Controls the maximum length/size of a query that will get logged when profiling or tracing | <code>2048</code> | 3.1.3 |
| <code>packetDebugBufferSize</code> | The maximum number of packets to retain when 'enablePacketDebug' is true | <code>20</code> | 3.1.3 |
| <code>slowQueryThresholdMillis</code> | If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'? | <code>2000</code> | 3.1.2 |
| <code>slowQueryThresholdNanos</code> | If 'useNanosForElapsedTime' is set to true, and this property is set to a non-zero value, the driver | <code>0</code> | 5.0.7 |

Connector/J (JDBC) Reference

| | | | |
|---|--|---|--------|
| | will use this threshold (in nanosecond units) to determine if a query was slow. | | |
| <code>useUsageAdvisor</code> | Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')? | <code>false</code> | 3.1.1 |
| <code>autoGenerateTestcaseScript</code> | Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR? | <code>false</code> | 3.1.9 |
| <code>autoSlowLog</code> | Instead of using <code>slowQueryThreshold*</code> to determine if a query is slow enough to be logged, maintain statistics that allow the driver to determine queries that are outside the 99th percentile? | <code>true</code> | 5.1.4 |
| <code>clientInfoProvider</code> | The name of a class that implements the <code>com.mysql.jdbc.JDBC4ClientInfoProvider</code> interface in order to support JDBC-4.0's <code>Connection.getClientInfo()</code> methods | <code>com.mysql.jdbc.JDBC4ClientInfoProvider</code> | 5.1.10 |
| <code>dumpMetadataOnColumnNotFoundException</code> | Should the driver dump the field-level metadata of a result set into the exception message when <code>ResultSet.findColumn()</code> fails? | <code>false</code> | 3.1.13 |
| <code>dumpQueriesOnException</code> | Should the driver dump the contents of the query sent to the server in the message for <code>SQLExceptions</code> ? | <code>false</code> | 3.1.3 |
| <code>enablePacketDebug</code> | When enabled, a ring-buffer of <code>'packetDebugBufferSize'</code> packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code | <code>false</code> | 3.1.3 |
| <code>explainSlowQueries</code> | If <code>'logSlowQueries'</code> is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level? | <code>false</code> | 3.1.2 |
| <code>includeInnodbStatusInDeadlockExceptions</code> | Include the output of "SHOW ENGINE INNODB STATUS" in exception messages when deadlock exceptions are detected? | <code>false</code> | 5.0.7 |
| <code>includeThreadDumpInDeadlockExceptions</code> | Include a current Java thread dump in exception messages when deadlock exceptions are detected? | <code>false</code> | 5.1.15 |
| <code>includeThreadNamesAsStatusInDeadlockExceptions</code> | Include the name of the current thread as a comment visible in "SHOW PROCESSLIST", or in Innodb deadlock dumps, useful in correlation with <code>"includeInnodbStatusInDeadlockExceptions=true"</code> and <code>"includeThreadDumpInDeadlockExceptions=true"</code> . | <code>false</code> | 5.1.15 |
| <code>logSlowQueries</code> | Should queries that take longer than <code>'slowQueryThresholdMillis'</code> be logged? | <code>false</code> | 3.1.2 |
| <code>logXaCommands</code> | Should the driver log XA commands sent by <code>MysqlXaConnection</code> to the server, at the DEBUG level of logging? | <code>false</code> | 5.0.5 |

| | | | |
|-------------------------------------|---|--|-------|
| <code>profilerEventHandler</code> | Name of a class that implements the interface <code>com.mysql.jdbc.profiler.ProfilerEventHandler</code> that will be used to handle profiling/tracing events. | <code>com.mysql.jdbc.profiler.I</code> | 5.1.6 |
| <code>resultSetSizeThreshold</code> | If the usage advisor is enabled, how many rows should a result set contain before the driver warns that it is suspiciously large? | 100 | 5.0.5 |
| <code>traceProtocol</code> | Should trace-level network protocol be logged? | <code>false</code> | 3.1.2 |
| <code>useNanosForElapsedTime</code> | For profiling/debugging functionality that measures elapsed time, should the driver try to use nanoseconds resolution if available (JDK >= 1.5)? | <code>false</code> | 5.0.7 |

Miscellaneous.

| Property Name | Definition | Default Value | Since Version |
|--|---|--------------------|---------------|
| <code>useUnicode</code> | Should the driver use Unicode character encodings when handling strings? Should only be used when the driver can't determine the character set mapping, or you are trying to 'force' the driver to use a character set that MySQL either doesn't natively support (such as UTF-8), true/false, defaults to 'true' | <code>true</code> | 1.1g |
| <code>characterEncoding</code> | If 'useUnicode' is set to true, what character encoding should the driver use when dealing with strings? (defaults is to 'autodetect') | | 1.1g |
| <code>characterSetResults</code> | Character set to tell the server to return results as. | | 3.0.13 |
| <code>connectionCollation</code> | If set, tells the server to use this collation via 'set collation_connection' | | 3.0.13 |
| <code>useBlobToStoreUTF8OutsideBmp</code> | Tells the driver to treat [MEDIUM/LONG]BLOB columns as [LONG]VARCHAR columns holding text encoded in UTF-8 that has characters outside the BMP (4-byte encodings), which MySQL server can't handle natively. | <code>false</code> | 5.1.3 |
| <code>utf8OutsideBmpExcludedColumnNamePattern</code> | When "useBlobToStoreUTF8OutsideBmp" is set to "true", column names matching the given regex will still be treated as BLOBs unless they match the regex specified for "utf8OutsideBmpIncludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package. | | 5.1.3 |
| <code>utf8OutsideBmpIncludedColumnNamePattern</code> | Used to specify exclusion rules to "utf8OutsideBmpExcludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package. | | 5.1.3 |
| <code>loadBalanceEnableJMX</code> | Enables JMX-based management of load-balanced connection groups, including live addition/removal of hosts from load-balancing pool. | <code>false</code> | 5.1.13 |
| <code>sessionVariables</code> | A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects. | | 3.1.8 |

| | | | |
|--|---|--------------------|--------|
| <code>useColumnNamesInFindColumns</code> | Prior to JDBC-4.0, the JDBC specification had a bug related to what could be given as a "column name" to <code>ResultSet</code> methods like <code>findColumn()</code> , or getters that took a <code>String</code> property. JDBC-4.0 clarified "column name" to mean the label, as given in an "AS" clause and returned by <code>ResultSetMetaData.getColumnLabel()</code> , and if no AS clause, the column name. Setting this property to "true" will give behavior that is congruent to JDBC-3.0 and earlier versions of the JDBC specification, but which because of the specification bug could give unexpected results. This property is preferred over "useOldAliasMetadataBehavior" unless you need the specific behavior that it provides with respect to <code>ResultSetMetadata</code> . | <code>false</code> | 5.1.7 |
| <code>allowNanAndInf</code> | Should the driver allow NaN or +/- INF values in <code>PreparedStatement.setDouble()</code> ? | <code>false</code> | 3.1.5 |
| <code>autoClosePstmtStreams</code> | Should the driver automatically call <code>.close()</code> on streams/readers passed as arguments via <code>set*()</code> methods? | <code>false</code> | 3.1.12 |
| <code>autoDeserialize</code> | Should the driver automatically detect and de-serialize objects stored in BLOB fields? | <code>false</code> | 3.1.5 |
| <code>blobsAreStrings</code> | Should the driver always treat BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses? | <code>false</code> | 5.0.8 |
| <code>capitalizeTypeNames</code> | Capitalize type names in <code>DatabaseMetaData</code> ? (usually only useful when using <code>WebObjects</code> , true/false, defaults to 'false') | <code>true</code> | 2.0.7 |
| <code>clobCharacterEncoding</code> | The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding | | 5.0.0 |
| <code>clobberStreamingResults</code> | This will cause a 'streaming' <code>ResultSet</code> to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server. | <code>false</code> | 3.0.9 |
| <code>compensateOnDuplicateKeys</code> | Should the driver compensate for the update counts of "ON DUPLICATE KEY" INSERT statements (2 = 1, 0 = 1) when using prepared statements? | <code>false</code> | 5.1.7 |
| <code>continueBatchOnError</code> | Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true'). | <code>true</code> | 3.0.3 |
| <code>createDatabaseIfNotExist</code> | Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases. | <code>false</code> | 3.1.9 |
| <code>emptyStringsConvertToZero</code> | Should the driver allow conversions from empty string fields to numeric values of '0'? | <code>true</code> | 3.1.8 |

Connector/J (JDBC) Reference

| | | | |
|---|---|--------------------|--------|
| <code>emulateLocators</code> | Should the driver emulate <code>java.sql.Blobs</code> with locators? With this feature enabled, the driver will delay loading the actual Blob data until the one of the retrieval methods (<code>getInputStream()</code> , <code>getBytes()</code> , and so forth) on the blob data stream has been accessed. For this to work, you must use a column alias with the value of the column to the actual name of the Blob. The feature also has the following restrictions: The SELECT that created the result set must reference only one table, the table must have a primary key; the SELECT must alias the original blob column name, specified as a string, to an alternate name; the SELECT must cover all columns that make up the primary key. | <code>false</code> | 3.1.0 |
| <code>emulateUnsupportedPstmts</code> | Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions? | <code>true</code> | 3.1.7 |
| <code>exceptionInterceptors</code> | Comma-delimited list of classes that implement <code>com.mysql.jdbc.ExceptionInterceptor</code> . These classes will be instantiated one per Connection instance, and all <code>SQLExceptions</code> thrown by the driver will be allowed to be intercepted by these interceptors, in a chained fashion, with the first class listed as the head of the chain. | | 5.1.8 |
| <code>functionsNeverReturnBlobs</code> | Should the driver always treat data from functions returning BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses? | <code>false</code> | 5.0.8 |
| <code>generateSimpleParameterMetadata</code> | Should the driver generate simplified parameter metadata for PreparedStatements when no metadata is available either because the server couldn't support preparing the statement, or server-side prepared statements are disabled? | <code>false</code> | 5.0.5 |
| <code>ignoreNonTxTables</code> | Ignore non-transactional table warning for rollback? (defaults to 'false'). | <code>false</code> | 3.0.9 |
| <code>jdbcCompliantTruncation</code> | Should the driver throw <code>java.sql.DataTruncation</code> exceptions when data is truncated as is required by the JDBC specification when connected to a server that supports warnings (MySQL 4.1.0 and newer)? This property has no effect if the server sql-mode includes <code>STRICT_TRANS_TABLES</code> . | <code>true</code> | 3.1.2 |
| <code>loadBalanceAutoCommitStatements</code> | When load-balancing is enabled for auto-commit statements (via <code>loadBalanceAutoCommitStatementThreshold</code>), the statement counter will only increment when the SQL matches the regular expression. By default, every statement issued matches. | | 5.1.15 |
| <code>loadBalanceAutoCommitStatementsThreshold</code> | When auto-commit is enabled, the number of statements which should be executed before triggering load-balancing to rebalance. Default | 0 | 5.1.15 |

Connector/J (JDBC) Reference

| | | | |
|--|---|------------------------------|--------------|
| | value of 0 causes load-balanced connections to only rebalance when exceptions are encountered, or auto-commit is disabled and transactions are explicitly committed or rolled back. | | |
| <code>loadBalanceBlacklistTime</code> | Time in milliseconds between checks of servers which are unavailable, by controlling how long a server lives in the global blacklist. | 0 | 5.1.0 |
| <code>loadBalanceConnectionGroup</code> | Logical group of load-balanced connections within a classloader, used to manage different groups independently. If not specified, live management of load-balanced connections is disabled. | | 5.1.13 |
| <code>loadBalanceExceptionChecker</code> | Fully-qualified class name of custom exception checker. The class must implement <code>com.mysql.jdbc.LoadBalanceExceptionChecker</code> interface, and is used to inspect <code>SQLException</code> s and determine whether they should trigger fail-over to another host in a load-balanced deployment. | <code>com.mysql.jdbc.</code> | 5.1.13 |
| <code>loadBalancePingTimeout</code> | Time in milliseconds to wait for ping response from each of load-balanced physical connections when using load-balanced Connection. | 0 | 5.1.13 |
| <code>loadBalanceSQLExceptions</code> | Comma-delimited list of classes/interfaces used by default load-balanced exception checker to determine whether a given <code>SQLException</code> should trigger failover. The comparison is done using <code>Class.isInstance(SQLException)</code> using the thrown <code>SQLException</code> . | | 5.1.13 |
| <code>loadBalanceSQLStateFailover</code> | Comma-delimited list of <code>SQLState</code> codes used by default load-balanced exception checker to determine whether a given <code>SQLException</code> should trigger failover. The <code>SQLState</code> of a given <code>SQLException</code> is evaluated to determine whether it begins with any value in the comma-delimited list. | | 5.1.13 |
| <code>loadBalanceValidateConnection</code> | Should the load-balanced Connection explicitly check whether the connection is live when swapping to a new physical connection at commit/rollback? | <code>false</code> | 5.1.13 |
| <code>maxRows</code> | The maximum number of rows to return (0, the default means return all rows). | -1 | all versions |
| <code>netTimeoutForStreamingResults</code> | What value should the driver automatically set the server setting 'net_write_timeout' to when the streaming result sets feature is in use? (value has unit of seconds, the value '0' means the driver will not try and adjust this value) | 600 | 5.1.0 |
| <code>noAccessToProcedureBodies</code> | When determining procedure parameter types for <code>CallableStatements</code> , and the connected user can't access procedure bodies through "SHOW CREATE PROCEDURE" or select on <code>mysql.proc</code> should the driver instead create basic metadata (all parameters reported as IN VARCHARs, but allowing <code>registerOutParameter()</code> to be called on them anyway) instead of throwing an exception? | <code>false</code> | 5.0.3 |

Connector/J (JDBC) Reference

| | | | |
|--|--|--------------------|--------|
| <code>noDatetimeStringSync</code> | Don't ensure that <code>ResultSet.getDatetimeType().toString().equals(ResultSet.getString())</code> | <code>false</code> | 3.1.7 |
| <code>noTimezoneConversionForTime</code> | Don't convert TIME values using the server timezone if 'useTimezone'='true' | <code>false</code> | 5.0.0 |
| <code>nullCatalogMeansCurrent</code> | When <code>DatabaseMetadataMethods</code> ask for a 'catalog' parameter, does the value null mean use the current catalog? (this is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver) | <code>true</code> | 3.1.8 |
| <code>nullNamePatternMatchesAll</code> | Should <code>DatabaseMeta</code> methods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification) | <code>true</code> | 3.1.8 |
| <code>overrideSupportsIntegrity</code> | Should the driver return "true" for <code>DatabaseMeta.supportsIntegrityEnhancementFacility()</code> even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being OpenOffice)? | <code>false</code> | 3.1.12 |
| <code>padCharsWithSpace</code> | If a result set column has the CHAR type and the value does not fill the amount of characters specified in the DDL for the column, should the driver pad the remaining characters with space (for ANSI compliance)? | <code>false</code> | 5.0.6 |
| <code>pedantic</code> | Follow the JDBC spec to the letter. | <code>false</code> | 3.0.0 |
| <code>pinGlobalTxToPhysicalConnection</code> | When using XAConnections, should the driver ensure that operations on a given XID are always routed to the same physical connection? This allows the XAConnection to support "XA START ... JOIN" after "XA END" has been called | <code>false</code> | 5.0.1 |
| <code>populateInsertRowWithDefaults</code> | When using ResultSets that are CONCUR_UPDATABLE, should the driver pre-populate the "insert" row with default values from the DDL for the table used in the query so those values are immediately available for ResultSet accessors? This functionality requires a call to the database for metadata each time a result set of this type is created. If disabled (the default), the default values will be populated by the an internal call to <code>refreshRow()</code> which pulls back default values and/or values changed by triggers. | <code>false</code> | 5.0.5 |
| <code>processEscapeCodesForPrepares</code> | Should the driver process escape codes in queries that are prepared? | <code>true</code> | 3.1.12 |
| <code>queryTimeoutKillsConnection</code> | If the timeout given in <code>Statement.setQueryTimeout()</code> expires, should the driver forcibly abort the Connection instead of attempting to abort the query? | <code>false</code> | 5.1.9 |

Connector/J (JDBC) Reference

| | | | |
|---|--|--------------------|--------|
| <code>relaxAutoCommit</code> | If the version of MySQL the driver connects to does not support transactions, still allow calls to <code>commit()</code> , <code>rollback()</code> and <code>setAutoCommit()</code> (true/false, defaults to 'false')? | <code>false</code> | 2.0.13 |
| <code>retainStatementAfterResultSetClose</code> | Should the driver retain the Statement reference in a ResultSet after <code>ResultSet.close()</code> has been called. This is not JDBC-compliant after JDBC-4.0. | <code>false</code> | 3.1.11 |
| <code>rollbackOnPooledClose</code> | Should the driver issue a <code>rollback()</code> when the logical connection in a pool is closed? | <code>true</code> | 3.0.15 |
| <code>runningCTS13</code> | Enables workarounds for bugs in Sun's JDBC compliance testsuite version 1.3 | <code>false</code> | 3.1.7 |
| <code>serverTimezone</code> | Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone | | 3.0.2 |
| <code>statementInterceptors</code> | A comma-delimited list of classes that implement "com.mysql.jdbc.StatementInterceptor" that should be placed "in between" query execution to influence the results. StatementInterceptors are "chainable", the results returned by the "current" interceptor will be passed on to the next in in the chain, from left-to-right order, as specified in this property. | | 5.1.1 |
| <code>strictFloatingPoint</code> | Used only in older versions of compliance test | <code>false</code> | 3.0.0 |
| <code>strictUpdates</code> | Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')? | <code>true</code> | 3.0.4 |
| <code>tinyIntIsBit</code> | Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)? | <code>true</code> | 3.0.16 |
| <code>transformedBitIsBoolean</code> | If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type? | <code>false</code> | 3.1.9 |
| <code>treatUtilDateAsTimestamp</code> | Should the driver treat <code>java.util.Date</code> as a <code>TIMESTAMP</code> for the purposes of <code>PreparedStatement.setObject()</code> ? | <code>true</code> | 5.0.5 |
| <code>ultraDevHack</code> | Create PreparedStatements for <code>prepareCall()</code> when required, because UltraDev is broken and issues a <code>prepareCall()</code> for <code>_all_</code> statements? (true/false, defaults to 'false') | <code>false</code> | 2.0.3 |
| <code>useAffectedRows</code> | Don't set the <code>CLIENT_FOUND_ROWS</code> flag when connecting to the server (not JDBC-compliant, will break most applications that rely on "found" rows vs. "affected rows" for DML statements), but does cause "correct" update counts from "INSERT ... ON DUPLICATE KEY UPDATE" statements to be returned by the server. | <code>false</code> | 5.1.7 |
| <code>useGmtMillisForDatetimes</code> | Convert between session timezone and GMT before creating Date and Timestamp instances (value | <code>false</code> | 3.1.12 |

Connector/J (JDBC) Reference

| | | | |
|---|--|--------------------|--------|
| | of "false" is legacy behavior, "true" leads to more JDBC-compliant behavior. | | |
| <code>useHostsInPrivileges</code> | Add '@hostname' to users in DatabaseMetaData.getColumn/TablePrivileges() (true/false), defaults to 'true'. | <code>true</code> | 3.0.2 |
| <code>useInformationSchema</code> | When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData? | <code>false</code> | 5.0.0 |
| <code>useJDBCCompliantTimezoneShift</code> | Should the driver use JDBC-compliant rules when converting TIME/TIMESTAMP/DATETIME values' timezone information for those JDBC arguments which take a java.util.Calendar argument? (Notice that this option is exclusive of the "useTimezone=true" configuration option.) | <code>false</code> | 5.0.0 |
| <code>useLegacyDatetimeCode</code> | Use code for DATE/TIME/DATETIME/TIMESTAMP handling in result sets and statements that consistently handles timezone conversions from client to server and back again, or use the legacy code for these datatypes that has been in the driver for backwards-compatibility? | <code>true</code> | 5.1.6 |
| <code>useOldAliasMetadataBehavior</code> | Should the driver use the legacy behavior for "AS" clauses on columns and tables, and only return aliases (if any) for ResultSetMetaData.getColumn() or ResultSetMetaData.getTable() rather than the original column/table name? In 5.0.x, the default value was true. | <code>false</code> | 5.0.4 |
| <code>useOldUTF8Behavior</code> | Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers | <code>false</code> | 3.1.6 |
| <code>useOnlyServerErrorMessage</code> | Don't prepend 'standard' SQLState error messages to error messages returned by the server. | <code>true</code> | 3.0.15 |
| <code>useSSPSCompatibleTimezoneShift</code> | If migrating from an environment that was using server-side prepared statements, and the configuration property "useJDBCCompliantTimezoneShift" set to "true", use compatible behavior when not using server-side prepared statements when sending TIMESTAMP values to the MySQL server. | <code>false</code> | 5.0.5 |
| <code>useServerPrepStmts</code> | Use server-side prepared statements if the server supports them? | <code>false</code> | 3.1.0 |
| <code>useSqlStateCodes</code> | Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true' | <code>true</code> | 3.1.3 |
| <code>useStreamLengthsInPrepStmts</code> | Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')? | <code>true</code> | 3.0.2 |
| <code>useTimezone</code> | Convert time/date types between client and server timezones (true/false, defaults to 'false')? | <code>false</code> | 3.0.2 |

| | | | |
|-----------------------------------|--|------------------------|--------|
| <code>useUnbufferedInput</code> | Don't use <code>BufferedInputStream</code> for reading data from the server | <code>true</code> | 3.0.11 |
| <code>yearIsDateType</code> | Should the JDBC driver treat the MySQL type "YEAR" as a <code>java.sql.Date</code> , or as a SHORT? | <code>true</code> | 3.1.9 |
| <code>zeroDateTimeBehavior</code> | What should happen when the driver encounters DATETIME values that are composed entirely of zeros (used by MySQL to represent invalid dates)? Valid values are "exception", "round" and "convertToNull". | <code>exception</code> | 3.1.4 |

Connector/J also supports access to MySQL using named pipes on Windows NT, Windows 2000, or Windows XP using the `NamedPipeSocketFactory` as a plugin-socket factory using the `socketFactory` property. If you do not use a `namedPipePath` property, the default of `'\\.\pipe\MySQL'` is used. If you use the `NamedPipeSocketFactory`, the host name and port number values in the JDBC url are ignored. To enable this feature, use:

```
socketFactory=com.mysql.jdbc.NamedPipeSocketFactory
```

Named pipes only work when connecting to a MySQL server on the same physical machine where the JDBC driver is running. In simple performance tests, named pipe access is between 30%-50% faster than the standard TCP/IP access. However, this varies per system, and named pipes are slower than TCP/IP in many Windows configurations.

To create your own socket factories, follow the example code in `com.mysql.jdbc.NamedPipeSocketFactory`, or `com.mysql.jdbc.StandardSocketFactory`.

22.3.5.1.1. Properties Files for the `useConfigs` Option

The `useConfigs` connection option is a convenient shorthand for specifying combinations of options for particular scenarios. The argument values you can use with this option correspond to the names of `.properties` files within the Connector/J `mysql-connector-java-version-bin.jar` JAR file. For example, the Connector/J 5.1.9 driver includes the following configuration properties files:

```
$ unzip mysql-connector-java-5.1.19-bin.jar '*/configs/*'
Archive:  mysql-connector-java-5.1.19-bin.jar
  creating:  com/mysql/jdbc/configs/
  inflating:  com/mysql/jdbc/configs/3-0-Compat.properties
  inflating:  com/mysql/jdbc/configs/5-0-Compat.properties
  inflating:  com/mysql/jdbc/configs/clusterBase.properties
  inflating:  com/mysql/jdbc/configs/coldFusion.properties
  inflating:  com/mysql/jdbc/configs/fullDebug.properties
  inflating:  com/mysql/jdbc/configs/maxPerformance.properties
  inflating:  com/mysql/jdbc/configs/solarisMaxPerformance.properties
```

To specify one of these combinations of options, specify `useConfigs=3-0-Compat`, `useConfigs=maxPerformance`, and so on. The following sections show the options that are part of each `useConfigs` setting. For the details of why each one is included, see the comments in the `.properties` files.

3-0-Compat

```
emptyStringsConvertToZero=true
jdbcCompliantTruncation=false
noDatetimeStringSync=true
nullCatalogMeansCurrent=true
nullNamePatternMatchesAll=true
transformedBitIsBoolean=false
dontTrackOpenResources=true
zeroDateTimeBehavior=convertToNull
useServerPrepStmts=false
```

```

autoClosePstmtStreams=true
processEscapeCodesForPrepStmts=false
useFastDateParsing=false
populateInsertRowWithDefaultValues=false
useDirectRowUnpack=false

```

5-0-Compat

```
useDirectRowUnpack=false
```

clusterBase

```

autoReconnect=true
failOverReadOnly=false
roundRobinLoadBalance=true

```

coldFusion

```

useDynamicCharsetInfo=false
alwaysSendSetIsolation=false
useLocalSessionState=true
autoReconnect=true

```

fullDebug

```

profileSQL=true
gatherPerMetrics=true
useUsageAdvisor=true
logSlowQueries=true
explainSlowQueries=true

```

maxPerformance

```

cachePrepStmts=true
cacheCallableStmts=true
cacheServerConfiguration=true
useLocalSessionState=true
elideSetAutoCommits=true
alwaysSendSetIsolation=false
enableQueryTimeouts=false

```

solarisMaxPerformance

```

useUnbufferedInput=false
useReadAheadInput=false
maintainTimeStats=false

```

22.3.5.2. JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly available version of Sun's JDBC compliance test suite. This section gives details on a interface-by-interface level about implementation decisions that might affect how you code applications with MySQL Connector/J. The JDBC specification is vague about how certain functionality should be implemented, or the specification enables leeway in implementation.

- **BLOB**

Starting with Connector/J version 3.1.0, you can emulate BLOBs with locators by adding the property `emulateLocators=true` to your JDBC URL. Using this method, the driver will delay loading the actual BLOB data until you retrieve the other data and then use retrieval methods (`getInputStream()`, `getBytes()`, and so forth) on the BLOB data stream.

You must use a column alias with the value of the column to the actual name of the BLOB, for example:

```
SELECT id, 'data' as blob_data from bloortable
```

You must also follow these rules:

- The `SELECT` must reference only one table. The table must have a [primary key](#).
- The `SELECT` must alias the original BLOB column name, specified as a string, to an alternate name.
- The `SELECT` must cover all columns that make up the primary key.

The BLOB implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, use the corresponding `PreparedStatement.setBlob()` or `ResultSet.updateBlob()` (in the case of updatable result sets) methods to save changes back to the database.

- **CallableStatement**

Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer using the `CallableStatement` interface. Currently, the `getParameterMetaData()` method of `CallableStatement` is not supported.

- **CLOB**

The CLOB implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, use the `PreparedStatement.setClob()` method to save changes back to the database. The JDBC API does not have a `ResultSet.updateClob()` method.

- **Connection**

Unlike the pre-Connector/J JDBC driver (`MM.MySQL`), the `isClosed()` method does not ping the server to determine if it is available. In accordance with the JDBC specification, it only returns true if `closed()` has been called on the connection. If you need to determine if the connection is still valid, issue a simple query, such as `SELECT 1`. The driver will throw an exception if the connection is no longer valid.

- **DatabaseMetaData**

[Foreign key](#) information (`getImportedKeys()/getExportedKeys()` and `getCrossReference()`) is only available from `InnoDB` tables. The driver uses `SHOW CREATE TABLE` to retrieve this information, so if any other storage engines add support for foreign keys, the driver would transparently support them as well.

- **PreparedStatement**

PreparedStatements are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement `getParameterMetaData()` or `getMetaData()` as it would require the driver to have a complete SQL parser in the client.

Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and binary-encoded result sets are used when the server supports them.

Take care when using a server-side prepared statement with **large** parameters that are set using `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()`, or `setClob()`. To re-execute the statement with any large parameter changed to a nonlarge parameter, call `clearParameters()` and set all parameters again. The reason for this is as follows:

- During both server-side prepared statements and client-side emulation, large data is exchanged only when `PreparedStatement.execute()` is called.

- Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and cannot be read from again.
- If a parameter changes from large to nonlarge, the driver must reset the server-side state of the prepared statement to allow the parameter that is being changed to take the place of the prior large value. This removes all of the large data that has already been sent to the server, thus requiring the data to be re-sent, using the `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()` or `setClob()` method.

Consequently, to change the type of a parameter to a nonlarge one, you must call `clearParameters()` and set all parameters of the prepared statement again before it can be re-executed.

- **ResultSet**

By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and cannot allocate heap space in your JVM for the memory required, you can tell the driver to stream the results back one row at a time.

To enable this functionality, create a `Statement` instance in the following manner:

```
stmt = conn.createStatement( java.sql.ResultSet.TYPE_FORWARD_ONLY,  
                             java.sql.ResultSet.CONCUR_READ_ONLY );  
stmt.setFetchSize( Integer.MIN_VALUE );
```

The combination of a forward-only, read-only result set, with a fetch size of `Integer.MIN_VALUE` serves as a signal to the driver to stream result sets row-by-row. After this, any result sets created with the statement will be retrieved row-by-row.

There are some caveats with this approach. You must read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

The earliest the locks these statements hold can be released (whether they be `MyISAM` table-level locks or row-level locks in some other storage engine such as `InnoDB`) is when the statement completes.

If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

Therefore, if using streaming results, process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- **ResultSetMetaData**

The `isAutoIncrement()` method only works when using MySQL servers 4.0 and newer.

- **Statement**

When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the `setFetchSize()` method has no effect, other than to toggle result set streaming as described above.

Connector/J 5.0.0 and later include support for both `Statement.cancel()` and `Statement.setQueryTimeout()`. Both require MySQL 5.0.0 or newer server, and require a separate connection to issue the `KILL QUERY` statement. In the case of `setQueryTimeout()`, the implementation creates an additional thread to handle the timeout functionality.

Note

Failures to cancel the statement for `setQueryTimeout()` may manifest themselves as `RuntimeException` rather than failing silently, as there is currently no way to unblock the thread that is executing the query being cancelled due to timeout expiration and have it throw the exception instead.

Note

The MySQL statement `KILL QUERY` (which is what the driver uses to implement `Statement.cancel()`) is non-deterministic; thus, avoid the use of `Statement.cancel()` if possible. If no query is in process, the next query issued will be killed by the server. This race condition is guarded against as of Connector/J 5.1.18.

MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so `setCursorName()` has no effect.

Connector/J 5.1.3 and later include two additional methods:

- `setLocalInfileInputStream()` sets an `InputStream` instance that will be used to send data to the MySQL server for a `LOAD DATA LOCAL INFILE` statement rather than a `FileInputStream` or `URLInputStream` that represents the path given as an argument to the statement.

This stream will be read to completion upon execution of a `LOAD DATA LOCAL INFILE` statement, and will automatically be closed by the driver, so it needs to be reset before each call to `execute*()` that would cause the MySQL server to request data to fulfill the request for `LOAD DATA LOCAL INFILE`.

If this value is set to `NULL`, the driver will revert to using a `FileInputStream` or `URLInputStream` as required.

- `getLocalInfileInputStream()` returns the `InputStream` instance that will be used to send data in response to a `LOAD DATA LOCAL INFILE` statement.

This method returns `NULL` if no such stream has been set using `setLocalInfileInputStream()`.

22.3.5.3. Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a `java.lang.String`, and any numeric type can be converted to any of the Java numeric types, although round-off, overflow, or loss of precision may occur.

Note

All `TEXT` types return `Types.LONGVARCHAR` with different `getPrecision()` values (65535, 255, 16777215, and 2147483647 respectively) with `getColumnType()` returning `-1`. This behavior is intentional even though

`TINYTEXT` does not fall, regarding to its size, within the `LONGVARCHAR` category. This is to avoid different handling inside the same base type. And `getColumnType()` returns `-1` because the internal server handling is of type `TEXT`, which is similar to `BLOB`.

Also note that `getColumnTypeName()` will return `VARCHAR` even though `getColumnType()` returns `Types.LONGVARCHAR`, because `VARCHAR` is the designated column database-specific name for this type.

Starting with Connector/J 3.1.0, the JDBC driver issues warnings or throws `DataTruncation` exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property `jdbcCompliantTruncation` and setting it to `false`.

The conversions that are always guaranteed to work are listed in the following table. The first column lists one or more MySQL data types, and the second column lists one or more Java types to which the MySQL types can be converted.

Table 22.24. Connection Properties - Miscellaneous

| These MySQL Data Types | Can always be converted to these Java types |
|---|---|
| <code>CHAR</code> , <code>VARCHAR</code> , <code>BLOB</code> , <code>TEXT</code> , <code>ENUM</code> , and <code>SET</code> | <code>java.lang.String</code> , <code>java.io.InputStream</code> , <code>java.io.Reader</code> , <code>java.sql.Blob</code> , <code>java.sql.Clob</code> |
| <code>FLOAT</code> , <code>REAL</code> , <code>DOUBLE PRECISION</code> , <code>NUMERIC</code> , <code>DECIMAL</code> , <code>TINYINT</code> , <code>SMALLINT</code> , <code>MEDIUMINT</code> , <code>INTEGER</code> , <code>BIGINT</code> | <code>java.lang.String</code> , <code>java.lang.Short</code> , <code>java.lang.Integer</code> , <code>java.lang.Long</code> , <code>java.lang.Double</code> , <code>java.math.BigDecimal</code> |
| <code>DATE</code> , <code>TIME</code> , <code>DATETIME</code> , <code>TIMESTAMP</code> | <code>java.lang.String</code> , <code>java.sql.Date</code> , <code>java.sql.Timestamp</code> |

Note

Round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.

The `ResultSet.getObject()` method uses the type conversions between MySQL and Java types, following the JDBC specification where appropriate. The value returned by `ResultSetMetaData.getColumnClassName()` is also shown below. For more information on the `java.sql.Types` classes see [Java 2 Platform Types](#).

Table 22.25. MySQL Types to Java Types for `ResultSet.getObject()`

| MySQL Type Name | Return value of <code>getColumnClassName</code> | Returned as Java Class |
|---|---|---|
| <code>BIT(1)</code> (new in MySQL-5.0) | <code>BIT</code> | <code>java.lang.Boolean</code> |
| <code>BIT(> 1)</code> (new in MySQL-5.0) | <code>BIT</code> | <code>byte[]</code> |
| <code>TINYINT</code> | <code>TINYINT</code> | <code>java.lang.Boolean</code> if the configuration property <code>tinyIntIsBit</code> is set to <code>true</code> (the default) and the storage size is 1, or <code>java.lang.Integer</code> if not. |
| <code>BOOL</code> , <code>BOOLEAN</code> | <code>TINYINT</code> | See <code>TINYINT</code> , above as these are aliases for <code>TINYINT(1)</code> , currently. |

| MySQL Type Name | Return value of <code>getColumnClassName</code> | Returned as Java Class |
|--|---|--|
| <code>SMALLINT[(M)] [UNSIGNED]</code> | <code>SMALLINT [UNSIGNED]</code> | <code>java.lang.Integer</code> (regardless if <code>UNSIGNED</code> or not) |
| <code>MEDIUMINT[(M)] [UNSIGNED]</code> | <code>MEDIUMINT [UNSIGNED]</code> | <code>java.lang.Integer</code> , if <code>UNSIGNED</code> <code>java.lang.Long</code> (C/J 3.1 and earlier), or <code>java.lang.Integer</code> for C/J 5.0 and later |
| <code>INT, INTEGER[(M)] [UNSIGNED]</code> | <code>INTEGER [UNSIGNED]</code> | <code>java.lang.Integer</code> , if <code>UNSIGNED</code> <code>java.lang.Long</code> |
| <code>BIGINT[(M)] [UNSIGNED]</code> | <code>BIGINT [UNSIGNED]</code> | <code>java.lang.Long</code> , if <code>UNSIGNED</code> <code>java.math.BigInteger</code> |
| <code>FLOAT[(M,D)]</code> | <code>FLOAT</code> | <code>java.lang.Float</code> |
| <code>DOUBLE[(M,B)]</code> | <code>DOUBLE</code> | <code>java.lang.Double</code> |
| <code>DECIMAL[(M[,D])]</code> | <code>DECIMAL</code> | <code>java.math.BigDecimal</code> |
| <code>DATE</code> | <code>DATE</code> | <code>java.sql.Date</code> |
| <code>DATETIME</code> | <code>DATETIME</code> | <code>java.sql.Timestamp</code> |
| <code>TIMESTAMP[(M)]</code> | <code>TIMESTAMP</code> | <code>java.sql.Timestamp</code> |
| <code>TIME</code> | <code>TIME</code> | <code>java.sql.Time</code> |
| <code>YEAR[(2 4)]</code> | <code>YEAR</code> | If <code>yearIsDateType</code> configuration property is set to <code>false</code> , then the returned object type is <code>java.sql.Short</code> . If set to <code>true</code> (the default), then the returned object is of type <code>java.sql.Date</code> with the date set to January 1st, at midnight. |
| <code>CHAR(M)</code> | <code>CHAR</code> | <code>java.lang.String</code> (unless the character set for the column is <code>BINARY</code> , then <code>byte[]</code> is returned. |
| <code>VARCHAR(M) [BINARY]</code> | <code>VARCHAR</code> | <code>java.lang.String</code> (unless the character set for the column is <code>BINARY</code> , then <code>byte[]</code> is returned. |
| <code>BINARY(M)</code> | <code>BINARY</code> | <code>byte[]</code> |
| <code>VARBINARY(M)</code> | <code>VARBINARY</code> | <code>byte[]</code> |
| <code>TINYBLOB</code> | <code>TINYBLOB</code> | <code>byte[]</code> |
| <code>TINYTEXT</code> | <code>VARCHAR</code> | <code>java.lang.String</code> |
| <code>BLOB</code> | <code>BLOB</code> | <code>byte[]</code> |
| <code>TEXT</code> | <code>VARCHAR</code> | <code>java.lang.String</code> |
| <code>MEDIUMBLOB</code> | <code>MEDIUMBLOB</code> | <code>byte[]</code> |
| <code>MEDIUMTEXT</code> | <code>VARCHAR</code> | <code>java.lang.String</code> |
| <code>LOBLOB</code> | <code>LOBLOB</code> | <code>byte[]</code> |
| <code>LONGTEXT</code> | <code>VARCHAR</code> | <code>java.lang.String</code> |
| <code>ENUM('value1', 'value2', ...)</code> | <code>CHAR..)</code> | <code>java.lang.String</code> |
| <code>SET('value1', 'value2', ...)</code> | <code>CHAR..)</code> | <code>java.lang.String</code> |

22.3.5.4. Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent using `Statement.execute()`,

`Statement.executeUpdate()`, `Statement.executeQuery()` as well as all `PreparedStatement` and `CallableStatement` parameters with the exclusion of parameters set using `setBytes()`, `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()` and `setBlob()`.

Number of Encodings Per Connection

In MySQL Server 4.1 and higher, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in `ResultSets`.

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the `useUnicode` and `characterEncoding` properties.

Setting the Character Encoding

The character encoding between client and server is automatically detected upon connection. You specify the encoding on the server using the `character_set_server` [488] for server versions 4.1.0 and newer, and `character_set` system variable for server versions older than 4.1.0. The driver automatically uses the encoding specified by the server. For more information, see [Section 10.1.3.1, “Server Character Set and Collation”](#).

For example, to use 4-byte UTF-8 character sets with Connector/J, configure the MySQL server with `character_set_server=utf8mb4` [488], and leave `characterEncoding` out of the Connector/J connection string. Connector/J will then autodetect the UTF-8 setting.

To override the automatically detected encoding on the client side, use the `characterEncoding` property in the URL used to connect to the server.

To allow multiple character sets to be sent from the client, use the UTF-8 encoding, either by configuring `utf8` as the default server character set, or by configuring the JDBC driver to use UTF-8 through the `characterEncoding` property.

When specifying character encodings on the client side, use Java-style names. The following table lists MySQL character set names and the corresponding Java-style names:

Table 22.26. MySQL to Java Encoding Name Translations

| MySQL Character Set Name | Java-Style Character Encoding Name |
|--------------------------|--|
| <code>ascii</code> | US-ASCII |
| <code>big5</code> | Big5 |
| <code>gbk</code> | GBK |
| <code>sjis</code> | SJIS (or Cp932 or MS932 for MySQL Server < 4.1.11) |
| <code>cp932</code> | Cp932 or MS932 (MySQL Server > 4.1.11) |
| <code>gb2312</code> | EUC_CN |
| <code>ujis</code> | EUC_JP |
| <code>euckr</code> | EUC_KR |
| <code>latin1</code> | Cp1252 |
| <code>latin2</code> | ISO8859_2 |
| <code>greek</code> | ISO8859_7 |
| <code>hebrew</code> | ISO8859_8 |

| MySQL Character Set Name | Java-Style Character Encoding Name |
|--------------------------|------------------------------------|
| <code>cp866</code> | <code>Cp866</code> |
| <code>tis620</code> | <code>TIS620</code> |
| <code>cp1250</code> | <code>Cp1250</code> |
| <code>cp1251</code> | <code>Cp1251</code> |
| <code>cp1257</code> | <code>Cp1257</code> |
| <code>macroman</code> | <code>MacRoman</code> |
| <code>macce</code> | <code>MacCentralEurope</code> |
| <code>utf8</code> | <code>UTF-8</code> |
| <code>ucs2</code> | <code>UnicodeBig</code> |

Warning

Do not issue the query `set names` with Connector/J, as the driver will not detect that the character set has changed, and will continue to use the character set detected during the initial connection setup.

22.3.5.5. Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: <http://developer.java.sun.com/developer/bugParade/bugs/4273544.html>
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL 4.0.4 or later. For more information, see [Section 6.3.8.2, “Configuring MySQL for SSL”](#).
- A client certificate (covered later in this section)

The system works through two Java truststore files, one file contains the certificate information for the server (`truststore` in the examples below). The other file contains the certificate for the client (`keystore` in the examples below). All Java truststore files are password protected by supplying a suitable password to the `keytool` when you create the files. You need the file names and associated passwords to create an SSL connection.

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the `SSL` subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server. Alternatively, use the CA Certificate that you have generated or been provided with by your SSL provider.

To use Java's `keytool` to create a truststore in the current directory, and import the server's CA certificate (`cacert.pem`), you can do the following (assuming that `keytool` is in your path. The `keytool` is typically located in the `bin` subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert \
  -file cacert.pem -keystore truststore
```

Enter the password when prompted for the keystore file. Interaction with `keytool` looks like this:

```
Enter keystore password: *****
```

```

Owner: EMAILADDRESS=walrus@example.com, CN=Walrus,
      O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus,
       O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Serial number: 0
Valid from:
  Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
  MD5:  61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
  SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]: yes
Certificate was added to keystore

```

You then have two options: either import the client certificate that matches the CA certificate you just imported, or create a new client certificate.

Importing an existing certificate requires the certificate to be in DER format. You can use [openssl](#) to convert an existing certificate into the new format. For example:

```
shell> openssl x509 -outform DER -in client-cert.pem -out client.cert
```

Now import the converted certificate into your keystore using [keytool](#):

```
shell> keytool -import -file client.cert -keystore keystore -alias mysqlClientCertificate
```

To generate your own client certificate, use [keytool](#) to create a suitable certificate and add it to the [keystore](#) file:

```
shell> keytool -genkey -keyalg rsa \
  -alias mysqlClientCertificate -keystore keystore
```

Keytool will prompt you for the following information, and create a keystore named [keystore](#) in the current directory.

Respond with information that is appropriate for your situation:

```

Enter keystore password: *****
What is your first and last name?
  [Unknown]: Matthews
What is the name of your organizational unit?
  [Unknown]: Software Development
What is the name of your organization?
  [Unknown]: MySQL AB
What is the name of your City or Locality?
  [Unknown]: Flossmoor
What is the name of your State or Province?
  [Unknown]: IL
What is the two-letter country code for this unit?
  [Unknown]: US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
  L=Flossmoor, ST=IL, C=US> correct?
  [no]: y

Enter key password for <mysqlClientCertificate>
  (RETURN if same as keystore password):

```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing [path_to_keystore_file](#) with the full path to the keystore file you created, [path_to_truststore_file](#) with the path to the truststore file you created, and using the appropriate password values for each property. You can do this either on the command line:

```

-Djavax.net.ssl.keyStore=path\_to\_keystore\_file
-Djavax.net.ssl.keyStorePassword=password
-Djavax.net.ssl.trustStore=path\_to\_truststore\_file

```

```
-Djavax.net.ssl.trustStorePassword=password
```

Or you can set the values directly within the application:

```
System.setProperty("javax.net.ssl.keyStore", "path_to_keystore_file");
System.setProperty("javax.net.ssl.keyStorePassword", "password");
System.setProperty("javax.net.ssl.trustStore", "path_to_truststore_file");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

You will also need to set `useSSL` to `true` in your connection parameters for MySQL Connector/J, either by adding `useSSL=true` to your URL, or by setting the property `useSSL` to `true` in the `java.util.Properties` instance you pass to `DriverManager.getConnection()`.

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```

```

JSSE provides debugging (to `stdout`) when you set the following system property: `-Djavax.net.debug=all`. This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

22.3.5.6. Connecting Using PAM Authentication

Java applications using Connector/J 5.1.21 and higher can connect to MySQL servers that use the pluggable authentication module (PAM) authentication scheme.

For PAM authentication to work, you must have the following:

- A MySQL server that supports PAM authentication: a commercial distribution of MySQL 5.5.16 or higher. See [Section 6.3.6.2, “The PAM Authentication Plugin”](#) for more information. Connector/J implements the same cleartext authentication method as in [Section 6.3.6.4, “The Cleartext Client-Side Authentication Plugin”](#).
- SSL capability, as explained in [Section 22.3.5.5, “Connecting Securely Using SSL”](#). Because the PAM authentication scheme sends the original password to the server, the connection to the server must be encrypted.

PAM authentication support is enabled by default in Connector/J 5.1.21 and up, so no extra configuration is needed.

To disable the PAM authentication feature, specify `mysql_clear_password` (the method) or `com.mysql.jdbc.authentication.MysqlClearPasswordPlugin` (the class name) in the comma-separated list of arguments for the `disabledAuthenticationPlugins` connection option. See [Section 22.3.5.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#) for details about that connection option.

22.3.5.7. Using Master/Slave Replication with ReplicationConnection

Connector/J 3.1.7 and higher includes a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()`.

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this replication-aware connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is sticky to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is time-sensitive (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the master MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the `com.mysql.jdbc.ReplicationDriver` class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager`-based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager`.

Here is a short example of how `ReplicationDriver` might be used in a standalone application:

```
import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

    public static void main(String[] args) throws Exception {
        ReplicationDriver driver = new ReplicationDriver();

        Properties props = new Properties();

        // We want this for failover on the slaves
        props.put("autoReconnect", "true");

        // We want to load balance between the slaves
```

```

props.put("roundRobinLoadBalance", "true");

props.put("user", "foo");
props.put("password", "bar");

//
// Looks like a normal MySQL JDBC url, with a
// comma-separated list of hosts, the first
// being the 'master', the rest being any number
// of slaves that the driver will load balance against
//

Connection conn =
    driver.connect("jdbc:mysql:replication://master,slave1,slave2,slave3/test",
        props);

//
// Perform read/write work on the master
// by setting the read-only flag to "false"
//

conn.setReadOnly(false);
conn.setAutoCommit(false);
conn.createStatement().executeUpdate("UPDATE some_table ...");
conn.commit();

//
// Now, do a query from a slave, the driver automatically picks one
// from the list
//

conn.setReadOnly(true);

ResultSet rs =
    conn.createStatement().executeQuery("SELECT a,b FROM alt_table");

    .....
}
}

```

Consider investigating the Load Balancing JDBC Pool ([lbpool](#)) tool, which provides a wrapper around the standard JDBC driver and enables you to use DB connection pools that includes checks for system failures and uneven load distribution. For more information, see [Load Balancing JDBC Pool \(lbpool\)](#).

22.3.5.8. Mapping MySQL Error Numbers to JDBC SQLState Codes

The table below provides a mapping of the MySQL error numbers to JDBC [SQLState](#) values.

Table 22.27. Mapping of MySQL Error Numbers to SQLStates

| MySQL Error Number | MySQL Error Name | Legacy (X/Open) SQLState | SQL Standard SQLState |
|--------------------|--|--------------------------|-----------------------|
| 1022 | ER_DUP_KEY | S1000 | 23000 |
| 1037 | ER_OUTOFMEMORY | S1001 | HY001 |
| 1038 | ER_OUT_OF_SORTMEMORY | S1001 | HY001 |
| 1040 | ER_CON_COUNT_ERROR | 08004 | 08004 |

22.3.6. JDBC Concepts

This section provides some general JDBC background.

22.3.6.1. Connecting to MySQL Using the JDBC `DriverManager` Interface

When you are using JDBC outside of an application server, the `DriverManager` class manages the establishment of Connections.

Specify to the `DriverManager` which JDBC drivers to try to make Connections with. The easiest way to do this is to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application. If testing this code, first read the installation section at [Section 22.3.3, “Connector/J Installation”](#), to make sure you have connector installed correctly and the `CLASSPATH` set up. Also, ensure that MySQL is configured to accept external TCP/IP connections.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
    public static void main(String[] args) {
        try {
            // The newInstance() call is a work around for some
            // broken Java implementations

            Class.forName("com.mysql.jdbc.Driver").newInstance();
        } catch (Exception ex) {
```

```

        // handle the error
    }
}

```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

Example 22.1. Connector/J: Obtaining a connection from the `DriverManager`

If you have not already done so, please review the section [Section 22.3.6.1, “Connecting to MySQL Using the JDBC `DriverManager` Interface”](#) before working with these examples.

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. Consult the API documentation that comes with your JDK for more specific information on how to use them.

```

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

Connection conn = null;
...
try {
    conn =
        DriverManager.getConnection("jdbc:mysql://localhost/test?" +
                                   "user=monty&password=greatsqlldb");

    // Do something with the Connection

    ...
} catch (SQLException ex) {
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}

```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

22.3.6.2. Using JDBC `Statement` Objects to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class, which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved using one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows matched by the update statement, not the number of rows that were modified.

If you do not know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE/INSERT`, then you can use the `execute(String SQL)` method. This method will return true if the SQL query was a `SELECT`, or false if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

Example 22.2. Connector/J: Using `java.sql.Statement` to execute a `SELECT` query

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;

// assume that conn is an already created JDBC connection (see previous examples)

Statement stmt = null;
ResultSet rs = null;

try {
    stmt = conn.createStatement();
    rs = stmt.executeQuery("SELECT foo FROM bar");

    // or alternatively, if you don't know ahead of time that
    // the query will be a SELECT...

    if (stmt.execute("SELECT foo FROM bar")) {
        rs = stmt.getResultSet();
    }

    // Now do something with the ResultSet ....
}
catch (SQLException ex){
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
finally {
    // it is a good idea to release
    // resources in a finally{} block
    // in reverse-order of their creation
    // if they are no-longer needed

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) { } // ignore

        rs = null;
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) { } // ignore

        stmt = null;
    }
}
```

22.3.6.3. Using JDBC `CallableStatements` to Execute Stored Procedures

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

For more information on MySQL stored procedures, please refer to <http://dev.mysql.com/doc/mysql/en/stored-routines.html>.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

**Note**

Current versions of MySQL server do not return enough information for the JDBC driver to provide result set metadata for callable statements. This means that when using `CallableStatement`, `ResultSetMetaData` may return `NULL`.

The following example shows a stored procedure that returns the value of `inOutParam` incremented by 1, and the string passed in using `inputParam` as a `ResultSet`:

Example 22.3. Connector/J: Calling Stored Procedures

```
CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), \
                       INOUT inOutParam INT)
BEGIN
  DECLARE z INT;
  SET z = inOutParam + 1;
  SET inOutParam = z;

  SELECT inputParam;

  SELECT CONCAT('zyxw', inputParam);
END
```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()`.

Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

Example 22.4. Connector/J: Using `Connection.prepareCall()`

```
import java.sql.CallableStatement;

...

//
// Prepare a call to the stored procedure 'demoSp'
// with two parameters
//
// Notice the use of JDBC-escape syntax ({call ...})
//

CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");

cStmt.setString(1, "abcdefg");
```

**Note**

`Connection.prepareCall()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, minimize unnecessary calls to `Connection.prepareCall()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

To retrieve the values of output parameters (parameters specified as `OUT` or `INOUT` when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

Example 22.5. Connector/J: Registering output parameters

```
import java.sql.Types;
...
//
// Connector/J supports both named and indexed
// output parameters. You can register output
// parameters using either method, as well
// as retrieve output parameters using either
// method, regardless of what method was
// used to register them.
//
// The following examples show how to use
// the various methods of registering
// output parameters (you should of course
// use only one registration per parameter).
//
//
// Registers the second parameter as output, and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter(2, Types.INTEGER);
//
// Registers the named parameter 'inOutParam', and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...
```

3. Set the input parameters (if any exist)

Input and in/out parameters are set as for [PreparedStatement](#) objects. However, [CallableStatement](#) also supports setting parameters by name:

Example 22.6. Connector/J: Setting [CallableStatement](#) input parameters

```
...
//
// Set a parameter by index
//
cStmt.setString(1, "abcdefg");
//
// Alternatively, set a parameter using
// the parameter name
//
cStmt.setString("inputParameter", "abcdefg");
//
// Set the 'in/out' parameter using an index
//
cStmt.setInt(2, 1);
//
// Alternatively, set the 'in/out' parameter
```

```

// by name
//
cStmt.setInt("inOutParam", 1);
...

```

4. Execute the `CallableStatement`, and retrieve any result sets or output parameters.

Although `CallableStatement` supports calling any of the `Statement` execute methods (`executeUpdate()`, `executeQuery()` or `execute()`), the most flexible method to call is `execute()`, as you do not need to know ahead of time if the stored procedure returns result sets:

Example 22.7. Connector/J: Retrieving results and output parameter values

```

...

boolean hadResults = cStmt.execute();

//
// Process all returned result sets
//

while (hadResults) {
    ResultSet rs = cStmt.getResultSet();

    // process result set
    ...

    hadResults = cStmt.getMoreResults();
}

//
// Retrieve output parameters
//
// Connector/J supports both index-based and
// name-based retrieval
//

int outputValue = cStmt.getInt(2); // index-based

outputValue = cStmt.getInt("inOutParam"); // name-based

...

```

22.3.6.4. Retrieving `AUTO_INCREMENT` Column Values through JDBC

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported auto increment or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC 3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC 3.0. The second example shows how you can retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value when using the `insertRow()` method.

Example 22.8. Connector/J: Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`

```
Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets assuming you have a
    // Connection 'conn' to a MySQL database already
    // available

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                               java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
        "CREATE TABLE autoIncTutorial ( "
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
        "INSERT INTO autoIncTutorial (dataField) "
        + "values ('Can I Get the Auto Increment Field?')",
        Statement.RETURN_GENERATED_KEYS);

    //
    // Example of using Statement.getGeneratedKeys()
    // to retrieve the value of an auto-increment
    // value
    //

    int autoIncKeyFromApi = -1;

    rs = stmt.getGeneratedKeys();

    if (rs.next()) {
        autoIncKeyFromApi = rs.getInt(1);
    } else {

        // throw an exception from here
    }

    rs.close();

    rs = null;

    System.out.println("Key returned from getGeneratedKeys():"
        + autoIncKeyFromApi);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

```

    }
}

if (stmt != null) {
    try {
        stmt.close();
    } catch (SQLException ex) {
        // ignore
    }
}
}
}

```

Example 22.9. Connector/J: Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`

```

Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets.

    stmt = conn.createStatement();

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
        "CREATE TABLE autoIncTutorial ("
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
        "INSERT INTO autoIncTutorial (dataField) "
        + "values ('Can I Get the Auto Increment Field?')");

    //
    // Use the MySQL LAST_INSERT_ID()
    // function to do the same thing as getGeneratedKeys()
    //

    int autoIncKeyFromFunc = -1;
    rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

    if (rs.next()) {
        autoIncKeyFromFunc = rs.getInt(1);
    } else {
        // throw an exception from here
    }

    rs.close();

    System.out.println("Key returned from " +
        "'SELECT LAST_INSERT_ID()': " +
        autoIncKeyFromFunc);

} finally {

```

```

if (rs != null) {
    try {
        rs.close();
    } catch (SQLException ex) {
        // ignore
    }
}

if (stmt != null) {
    try {
        stmt.close();
    } catch (SQLException ex) {
        // ignore
    }
}
}

```

Example 22.10. Connector/J: Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`

```

Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets as well as an 'updatable'
    // one, assuming you have a Connection 'conn' to
    // a MySQL database already available
    //

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                                java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
        "CREATE TABLE autoIncTutorial ("
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Example of retrieving an AUTO INCREMENT key
    // from an updatable result set
    //

    rs = stmt.executeQuery("SELECT priKey, dataField "
        + "FROM autoIncTutorial");

    rs.moveToInsertRow();

    rs.updateString("dataField", "AUTO INCREMENT here?");
    rs.insertRow();

    //
    // the driver adds rows at the end
    //

    rs.last();

    //
    // We should now be on the row we just inserted
    //

```

```
int autoIncKeyFromRS = rs.getInt("priKey");

rs.close();

rs = null;

System.out.println("Key returned for inserted row: "
    + autoIncKeyFromRS);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}
```

Running the preceding example code should produce the following output:

```
Key returned from getGeneratedKeys(): 1
Key returned from SELECT LAST_INSERT_ID(): 1
Key returned for inserted row: 2
```

At times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value is overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

22.3.7. Connection Pooling with Connector/J

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any [thread](#) that needs them. Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage.

How Connection Pooling Works

Most applications only need a thread to have access to a JDBC connection when they are actively processing a [transaction](#), which often takes only milliseconds to complete. When not processing a transaction, the connection sits idle. Connection pooling enables the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it can be used by any other threads.

When the connection is loaned out from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called `DriverManager.getConnection()` every time it needed a JDBC connection. With connection pooling, your thread may end up using either a new connection or an already-existing connection.

Benefits of Connection Pooling

The main benefits to connection pooling are:

- Reduced connection creation time.

Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are recycled.

- Simplified programming model.

When using connection pooling, each individual thread can act as though it has created its own JDBC connection, allowing you to use straightforward JDBC programming techniques.

- Controlled resource usage.

If you create a new connection every time a thread needs one, rather than using connection pooling, your application's resource usage can be wasteful and lead to unpredictable behavior under load.

Using Connection Pooling with Connector/J

Sun has standardized the concept of connection pooling in JDBC through the JDBC 2.0 Optional interfaces, and all major application servers have implementations of these APIs that work with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it through the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

Example 22.11. Connector/J: Using a connection pool with a J2EE application server

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

    public void doSomething() throws Exception {
        /*
         * Create a JNDI Initial context to be able to
         * lookup the DataSource
         *
         * In production-level code, this should be cached as
         * an instance or static variable, as it can
         * be quite expensive to create a JNDI context.
         *
         * Note: This code only works when you are using servlets
         * or EJBs in a J2EE application server. If you are
         * using connection pooling in standalone Java code, you
         * will have to create/configure datasources using whatever
         * mechanisms your particular connection pooling library
         * provides.
         */

        InitialContext ctx = new InitialContext();

        /*
         * Lookup the DataSource, which will be backed by a pool
         */
    }
}
```

```
* that the application server provides. DataSource instances
* are also a good candidate for caching as an instance
* variable, as JNDI lookups can be expensive as well.
*/

DataSource ds =
    (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");

/*
 * The following code is what would actually be in your
 * Servlet, JSP or EJB 'service' method...where you need
 * to work with a JDBC connection.
 */

Connection conn = null;
Statement stmt = null;

try {
    conn = ds.getConnection();

    /*
     * Now, use normal JDBC programming to work with
     * MySQL, making sure to close each resource when you're
     * finished with it, which permits the connection pool
     * resources to be recovered as quickly as possible
     */

    stmt = conn.createStatement();
    stmt.execute("SOME SQL QUERY");

    stmt.close();
    stmt = null;

    conn.close();
    conn = null;
} finally {
    /*
     * close any jdbc instances here that weren't
     * explicitly closed during normal code path, so
     * that we don't 'leak' resources...
     */

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlex) {
            // ignore, as we can't do anything about it here
        }

        stmt = null;
    }

    if (conn != null) {
        try {
            conn.close();
        } catch (SQLException sqlex) {
            // ignore, as we can't do anything about it here
        }

        conn = null;
    }
}
}
```

As shown in the example above, after obtaining the JNDI [InitialContext](#), and looking up the [DataSource](#), the rest of the code follows familiar JDBC conventions.

When using connection pooling, always make sure that connections, and anything created by them (such as statements or result sets) are closed. This rule applies no matter what happens in your code (exceptions, flow-of-control, and so forth). When these objects are closed, they can be re-used; otherwise, they will be stranded, which means that the MySQL server resources they represent (such as buffers, locks, or sockets) are tied up for some time, or in the worst case can be tied up forever.

Sizing the Connection Pool

Each connection to MySQL has overhead (memory, CPU, context switches, and so forth) on both the client and server side. Every connection limits how many resources there are available to your application as well as the MySQL server. Many of these resources will be used whether or not the connection is actually doing any useful work! Connection pools can be tuned to maximize performance, while keeping resource utilization below the point where your application will start to fail rather than just run slower.

The optimal size for the connection pool depends on anticipated load and average database transaction time. In practice, the optimal connection pool size can be smaller than you might expect. If you take Sun's Java Petstore blueprint application for example, a connection pool of 15-20 connections can serve a relatively moderate load (600 concurrent users) using MySQL and Tomcat with acceptable response times.

To correctly size a connection pool for your application, create load test scripts with tools such as Apache JMeter or The Grinder, and load test your application.

An easy way to determine a starting point is to configure your connection pool's maximum number of connections to be unbounded, run a load test, and measure the largest amount of concurrently used connections. You can then work backward from there to determine what values of minimum and maximum pooled connections give the best performance for your particular application.

Validating Connections

MySQL Connector/J can validate the connection by executing a lightweight ping against a server. In the case of load-balanced connections, this is performed against all active pooled internal connections that are retained. This is beneficial to Java applications using connection pools, as the pool can use this feature to validate connections. Depending on your connection pool and configuration, this validation can be carried out at different times:

1. Before the pool returns a connection to the application.
2. When the application returns a connection to the pool.
3. During periodic checks of idle connections.

To use this feature, specify a validation query in your connection pool that starts with `/* ping */`. Note that the syntax must be exactly as specified. This will cause the driver send a ping to the server and return a dummy lightweight result set. When using a [ReplicationConnection](#) or [LoadBalancedConnection](#), the ping will be sent across all active connections.

It is critical that the syntax be specified correctly. The syntax needs to be exact for reasons of efficiency, as this test is done for every statement that is executed:

```
protected static final String PING_MARKER = "/* ping */";
...
if (sql.charAt(0) == '/') {
if (sql.startsWith(PING_MARKER)) {
doPingInstead();
...
}
```

None of the following snippets will work, because the ping syntax is sensitive to whitespace, capitalization, and placement:

```
sql = "/* PING */ SELECT 1";
sql = "SELECT 1 /* ping*/";
sql = "/*ping*/ SELECT 1";
sql = " /* ping */ SELECT 1";
sql = "/*to ping or not to ping*/ SELECT 1";
```

All of the previous statements will issue a normal `SELECT` statement and will **not** be transformed into the lightweight ping. Further, for load-balanced connections, the statement will be executed against one connection in the internal pool, rather than validating each underlying physical connection. This results in the non-active physical connections assuming a stale state, and they may die. If Connector/J then re-balances, it might select a dead connection, resulting in an exception being passed to the application. To help prevent this, you can use `loadBalanceValidateConnectionOnSwapServer` to validate the connection before use.

If your Connector/J deployment uses a connection pool that allows you to specify a validation query, take advantage of it, but ensure that the query starts *exactly* with `/* ping */`. This is particularly important if you are using the load-balancing or replication-aware features of Connector/J, as it will help keep alive connections which otherwise will go stale and die, causing problems later.

22.3.8. Load Balancing with Connector/J

Connector/J has long provided an effective means to distribute read/write load across multiple MySQL server instances for Cluster or master-master replication deployments. Starting with Connector/J 5.1.3, you can now dynamically configure load-balanced connections, with no service outage. In-process transactions are not lost, and no application exceptions are generated if any application is trying to use that particular server instance.

There are two connection string options associated with this functionality:

- `loadBalanceConnectionGroup` – This provides the ability to group connections from different sources. This allows you to manage these JDBC sources within a single class loader in any combination you choose. If they use the same configuration, and you want to manage them as a logical single group, give them the same name. This is the key property for management: if you do not define a name (string) for `loadBalanceConnectionGroup`, you cannot manage the connections. All load-balanced connections sharing the same `loadBalanceConnectionGroup` value, regardless of how the application creates them, will be managed together.
- `loadBalanceEnableJMX` – The ability to manage the connections is exposed when you define a `loadBalanceConnectionGroup`, but if you want to manage this externally, enable JMX by setting this property to `true`. This enables a JMX implementation, which exposes the management and monitoring operations of a connection group. Further, start your application with the `-Dcom.sun.management.jmxremote` JVM flag. You can then perform connect and perform operations using a JMX client such as `jconsole`.

Once a connection has been made using the correct connection string options, a number of monitoring properties are available:

- Current active host count.
- Current active physical connection count.
- Current active logical connection count.
- Total logical connections created.
- Total transaction count.

The following management operations can also be performed:

- Add host.
- Remove host.

The JMX interface, `com.mysql.jdbc.jmx.LoadBalanceConnectionGroupManagerMBean`, has the following methods:

- `int getActiveHostCount(String group);`
- `int getTotalHostCount(String group);`
- `long getTotalLogicalConnectionCount(String group);`
- `long getActiveLogicalConnectionCount(String group);`
- `long getActivePhysicalConnectionCount(String group);`
- `long getTotalPhysicalConnectionCount(String group);`
- `long getTotalTransactionCount(String group);`
- `void removeHost(String group, String host) throws SQLException;`
- `void stopNewConnectionsToHost(String group, String host) throws SQLException;`
- `void addHost(String group, String host, boolean forExisting);`
- `String getActiveHostsList(String group);`
- `String getRegisteredConnectionGroups();`

The `getRegisteredConnectionGroups()` method returns the names of all connection groups defined in that class loader.

You can test this setup with the following code:

```
public class Test {

    private static String URL = "jdbc:mysql:loadbalance://" +
        "localhost:3306,localhost:3310/test?" +
        "loadBalanceConnectionGroup=first&loadBalanceEnableJMX=true";

    public static void main(String[] args) throws Exception {
        new Thread(new Repeater()).start();
        new Thread(new Repeater()).start();
        new Thread(new Repeater()).start();
    }

    static Connection getNewConnection() throws SQLException, ClassNotFoundException {
        Class.forName("com.mysql.jdbc.Driver");
        return DriverManager.getConnection(URL, "root", "");
    }

    static void executeSimpleTransaction(Connection c, int conn, int trans){
        try {
            c.setAutoCommit(false);
            Statement s = c.createStatement();
            s.executeQuery("SELECT SLEEP(1) /* Connection: " + conn + ", transaction: " + trans + " */");
            c.commit();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

```

public static class Repeater implements Runnable {
    public void run() {
        for(int i=0; i < 100; i++){
            try {
                Connection c = getNewConnection();
                for(int j=0; j < 10; j++){
                    executeSimpleTransaction(c, i, j);
                    Thread.sleep(Math.round(100 * Math.random()));
                }
                c.close();
                Thread.sleep(100);
            } catch (Exception e) {
                e.printStackTrace();
            }
        }
    }
}

```

After compiling, the application can be started with the `-Dcom.sun.management.jmxremote` flag, to enable remote management. `jconsole` can then be started. The `Test` main class will be listed by `jconsole`. Select this and click **Connect**. You can then navigate to the `com.mysql.jdbc.jmx.LoadBalanceConnectionGroupManager` bean. At this point, you can click on various operations and examine the returned result.

If you now had an additional instance of MySQL running on port 3309, you could ensure that Connector/J starts using it by using the `addHost()`, which is exposed in `jconsole`. Note that these operations can be performed dynamically without having to stop the application running.

For further information on the combination of load balancing and failover, see [Section 22.3.9, "Failover with Connector/J"](#).

22.3.9. Failover with Connector/J

Connector/J provides a useful load-balancing implementation for Cluster or multi-master deployments, as explained in [Section 22.3.8, "Load Balancing with Connector/J"](#). As of Connector/J 5.1.12, this same implementation is used for balancing load between read-only slaves with `ReplicationDriver`. When trying to balance workload between multiple servers, the driver has to determine when it is safe to swap servers, doing so in the middle of a transaction, for example, could cause problems. It is important not to lose state information. For this reason, Connector/J will only try to pick a new server when one of the following happens:

1. At transaction boundaries (transactions are explicitly committed or rolled back).
2. A communication exception (SQL State starting with "08") is encountered.
3. When a `SQLException` matches conditions defined by user, using the extension points defined by the `loadBalanceSQLStateFailover`, `loadBalanceSQLExceptionSubclassFailover` or `loadBalanceExceptionChecker` properties.

The third condition revolves around three new properties introduced with Connector/J 5.1.13. It allows you to control which `SQLExceptions` trigger failover.

- `loadBalanceExceptionChecker` - The `loadBalanceExceptionChecker` property is really the key. This takes a fully-qualified class name which implements the new `com.mysql.jdbc.LoadBalanceExceptionChecker` interface. This interface is very simple, and you only need to implement the following method:

```
public boolean shouldExceptionTriggerFailover(SQLException ex)
```

A `SQLException` is passed in, and a boolean returned. A value of `true` triggers a failover, `false` does not.

You can use this to implement your own custom logic. An example where this might be useful is when dealing with transient errors when using MySQL Cluster, where certain buffers may become overloaded. The following code snippet illustrates this:

```
public class NdbLoadBalanceExceptionChecker
    extends StandardLoadBalanceExceptionChecker {

    public boolean shouldExceptionTriggerFailover(SQLException ex) {
        return super.shouldExceptionTriggerFailover(ex)
            || checkNdbException(ex);
    }

    private boolean checkNdbException(SQLException ex){
        // Have to parse the message since most NDB errors
        // are mapped to the same DEMC.
        return (ex.getMessage().startsWith("Lock wait timeout exceeded") ||
            (ex.getMessage().startsWith("Got temporary error")
            && ex.getMessage().endsWith("from NDB")));
    }
}
```

The code above extends `com.mysql.jdbc.StandardLoadBalanceExceptionChecker`, which is the default implementation. There are a few convenient shortcuts built into this, for those who want to have some level of control using properties, without writing Java code. This default implementation uses the two remaining properties: `loadBalanceSQLStateFailover` and `loadBalanceSQLExceptionSubclassFailover`.

- `loadBalanceSQLStateFailover` - allows you to define a comma-delimited list of `SQLState` code prefixes, against which a `SQLException` is compared. If the prefix matches, failover is triggered. So, for example, the following would trigger a failover if a given `SQLException` starts with "00", or is "12345":

```
loadBalanceSQLStateFailover=00,12345
```

- `loadBalanceSQLExceptionSubclassFailover` - can be used in conjunction with `loadBalanceSQLStateFailover` or on its own. If you want certain subclasses of `SQLException` to trigger failover, simply provide a comma-delimited list of fully-qualified class or interface names to check against. For example, if you want all `SQLTransientConnectionExceptions` to trigger failover, you would specify:

```
loadBalanceSQLExceptionSubclassFailover=java.sql.SQLTransientConnectionException
```

While the three fail-over conditions enumerated earlier suit most situations, if `auto-commit` is enabled, Connector/J never re-balances, and continues using the same physical connection. This can be problematic, particularly when load-balancing is being used to distribute read-only load across multiple slaves. However, Connector/J can be configured to re-balance after a certain number of statements are executed, when `auto-commit` is enabled. This functionality is dependent upon the following properties:

- `loadBalanceAutoCommitStatementThreshold` – defines the number of matching statements which will trigger the driver to potentially swap physical server connections. The default value, 0, retains the behavior that connections with `auto-commit` enabled are never balanced.
- `loadBalanceAutoCommitStatementRegex` – the regular expression against which statements must match. The default value, blank, matches all statements. So, for example, using the following properties will cause Connector/J to re-balance after every third statement that contains the string "test":

```
loadBalanceAutoCommitStatementThreshold=3
loadBalanceAutoCommitStatementRegex=.*test.*
```

`loadBalanceAutoCommitStatementRegex` can prove useful in a number of situations. Your application may use temporary tables, server-side session state variables, or connection state, where letting the driver arbitrarily swap physical connections before processing is complete could cause data loss or other problems. This allows you to identify a trigger statement that is only executed when it is safe to swap physical connections.

22.3.10. Using the Connector/J Interceptor Classes

An interceptor is a software design pattern that provides a transparent way to extend or modify some aspect of a program, similar to a user exit. No recompiling is required. With Connector/J, the interceptors are enabled and disabled by updating the connection string to refer to different sets of interceptor classes that you instantiate.

The connection properties that control the interceptors are explained in [Section 22.3.5.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”](#):

- `connectionLifecycleInterceptors`, where you specify the fully qualified names of classes that implement the `com.mysql.jdbc.ConnectionLifecycleInterceptor` interface. In these kinds of interceptor classes, you might log events such as rollbacks, measure the time between transaction start and end, or count events such as calls to `setAutoCommit()`.
- `exceptionInterceptors`, where you specify the fully qualified names of classes that implement the `com.mysql.jdbc.ExceptionInterceptor` interface. In these kinds of interceptor classes, you might add extra diagnostic information to exceptions that can have multiple causes or indicate a problem with server settings. Because `exceptionInterceptors` classes are only called when handling a `SQLException` thrown from Connector/J code, they can be used even in production deployments without substantial performance overhead.
- `statementInterceptors`, where you specify the fully qualified names of classes that implement the `com.mysql.jdbc.StatementInterceptorV2` interface. In these kinds of interceptor classes, you might change or augment the processing done by certain kinds of statements, such as automatically checking for queried data in a `memcached` server, rewriting slow queries, logging information about statement execution, or route requests to remote servers.

22.3.11. Using Connector/J with Tomcat

The following instructions are based on the instructions for Tomcat-5.x, available at <http://tomcat.apache.org/tomcat-5.5-doc/jndi-datasource-examples-howto.html> which is current at the time this document was written.

First, install the `.jar` file that comes with Connector/J in `$(CATALINA_HOME)/common/lib` so that it is available to all applications installed in the container.

Next, configure the JNDI DataSource by adding a declaration resource to `$(CATALINA_HOME)/conf/server.xml` in the context that defines your web application:

```
<Context ....>
...
<Resource name="jdbc/MySQLDB"
  auth="Container"
  type="javax.sql.DataSource"/>
```

```
<ResourceParams name="jdbc/MySQLDB">
  <parameter>
    <name>factory</name>
    <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
  </parameter>

  <parameter>
    <name>maxActive</name>
    <value>10</value>
  </parameter>

  <parameter>
    <name>maxIdle</name>
    <value>5</value>
  </parameter>

  <parameter>
    <name>validationQuery</name>
    <value>SELECT 1</value>
  </parameter>

  <parameter>
    <name>testOnBorrow</name>
    <value>true</value>
  </parameter>

  <parameter>
    <name>testWhileIdle</name>
    <value>true</value>
  </parameter>

  <parameter>
    <name>timeBetweenEvictionRunsMillis</name>
    <value>10000</value>
  </parameter>

  <parameter>
    <name>minEvictableIdleTimeMillis</name>
    <value>60000</value>
  </parameter>

  <parameter>
    <name>username</name>
    <value>someuser</value>
  </parameter>

  <parameter>
    <name>password</name>
    <value>somepass</value>
  </parameter>

  <parameter>
    <name>driverClassName</name>
    <value>com.mysql.jdbc.Driver</value>
  </parameter>

  <parameter>
    <name>url</name>
    <value>jdbc:mysql://localhost:3306/test</value>
  </parameter>

</ResourceParams>
</Context>
```

Note that Connector/J 5.1.3 introduced a facility whereby, rather than use a `validationQuery` value of `SELECT 1`, it is possible to use `validationQuery` with a value set to `/* ping */`. This sends a ping to

the server which then returns a fake result set. This is a lighter weight solution. It also has the advantage that if using [ReplicationConnection](#) or [LoadBalancedConnection](#) type connections, the ping will be sent across all active connections. The following XML snippet illustrates how to select this option:

```
<parameter>
  <name>validationQuery</name>
  <value>/* ping */</value>
</parameter>
```

Note that `/* ping */` has to be specified exactly.

In general, follow the installation instructions that come with your version of Tomcat, as the way you configure datasources in Tomcat changes from time to time, and if you use the wrong syntax in your XML file, you will most likely end up with an exception similar to the following:

```
Error: java.sql.SQLException: Cannot load JDBC driver class 'null ' SQL
state: null
```

Note that the auto-loading of drivers having the `META-INF/service/java.sql.Driver` class in JDBC 4.0 causes an improper undeployment of the Connector/J driver in Tomcat on Windows. Namely, the Connector/J jar remains locked. This is an initialization problem that is not related to the driver. The possible workarounds, if viable, are as follows: use `antiResourceLocking=true` as a Tomcat Context attribute, or remove the `META-INF/` directory.

22.3.12. Using Connector/J with JBoss

These instructions cover JBoss-4.x. To make the JDBC driver classes available to the application server, copy the `.jar` file that comes with Connector/J to the `lib` directory for your server configuration (which is usually called `default`). Then, in the same configuration directory, in the subdirectory named `deploy`, create a datasource configuration file that ends with `-ds.xml`, which tells JBoss to deploy this file as a JDBC Datasource. The file should have the following contents:

```
<datasources>
  <local-tx-datasource>

    <jndi-name>MySQLDB</jndi-name>
    <connection-url>jdbc:mysql://localhost:3306/dbname</connection-url>
    <driver-class>com.mysql.jdbc.Driver</driver-class>
    <user-name>user</user-name>
    <password>pass</password>

</datasources>
```

22.3.13. Using Connector/J with Spring

The Spring Framework is a Java-based application framework designed for assisting in application design by providing a way to configure components. The technique used by Spring is a well known design pattern

called Dependency Injection (see [Inversion of Control Containers and the Dependency Injection pattern](#)). This article will focus on Java-oriented access to MySQL databases with Spring 2.0. For those wondering, there is a .NET port of Spring appropriately named Spring.NET.

Spring is not only a system for configuring components, but also includes support for aspect oriented programming (AOP). This is one of the main benefits and the foundation for Spring's resource and transaction management. Spring also provides utilities for integrating resource management with JDBC and Hibernate.

For the examples in this section the MySQL world sample database will be used. The first task is to set up a MySQL data source through Spring. Components within Spring use the "bean" terminology. For example, to configure a connection to a MySQL server supporting the world sample database, you might use:

```
<util:map id="dbProps">
  <entry key="db.driver" value="com.mysql.jdbc.Driver"/>
  <entry key="db.jdbcurl" value="jdbc:mysql://localhost/world"/>
  <entry key="db.username" value="myuser"/>
  <entry key="db.password" value="mypass"/>
</util:map>
```

In the above example, we are assigning values to properties that will be used in the configuration. For the datasource configuration:

```
<bean id="dataSource"
      class="org.springframework.jdbc.datasource.DriverManagerDataSource">
  <property name="driverClassName" value="${db.driver}"/>
  <property name="url" value="${db.jdbcurl}"/>
  <property name="username" value="${db.username}"/>
  <property name="password" value="${db.password}"/>
</bean>
```

The placeholders are used to provide values for properties of this bean. This means that you can specify all the properties of the configuration in one place instead of entering the values for each property on each bean. We do, however, need one more bean to pull this all together. The last bean is responsible for actually replacing the placeholders with the property values.

```
<bean
  class="org.springframework.beans.factory.config.PropertyPlaceholderConfigurer">
  <property name="properties" ref="dbProps"/>
</bean>
```

Now that we have our MySQL data source configured and ready to go, we write some Java code to access it. The example below will retrieve three random cities and their corresponding country using the data source we configured with Spring.

```
// Create a new application context. this processes the Spring config
ApplicationContext ctx =
  new ClassPathXmlApplicationContext("exlappContext.xml");
// Retrieve the data source from the application context
DataSource ds = (DataSource) ctx.getBean("dataSource");
// Open a database connection using Spring's DataSourceUtils
Connection c = DataSourceUtils.getConnection(ds);
try {
  // retrieve a list of three random cities
  PreparedStatement ps = c.prepareStatement(
    "select City.Name as 'City', Country.Name as 'Country' " +
    "from City inner join Country on City.CountryCode = Country.Code " +
    "order by rand() limit 3");
  ResultSet rs = ps.executeQuery();
  while(rs.next()) {
```

```
        String city = rs.getString("City");
        String country = rs.getString("Country");
        System.out.printf("The city %s is in %s%n", city, country);
    }
} catch (SQLException ex) {
    // something has failed and we print a stack trace to analyse the error
    ex.printStackTrace();
    // ignore failure closing connection
    try { c.close(); } catch (SQLException e) { }
} finally {
    // properly release our connection
    DataSourceUtils.releaseConnection(c, ds);
}
```

This is very similar to normal JDBC access to MySQL with the main difference being that we are using `DataSourceUtils` instead of the `DriverManager` to create the connection.

While it may seem like a small difference, the implications are somewhat far reaching. Spring manages this resource in a way similar to a container managed data source in a J2EE application server. When a connection is opened, it can be subsequently accessed in other parts of the code if it is synchronized with a transaction. This makes it possible to treat different parts of your application as transactional instead of passing around a database connection.

22.3.13.1. Using `JdbcTemplate`

Spring makes extensive use of the Template method design pattern (see [Template Method Pattern](#)). Our immediate focus will be on the `JdbcTemplate` and related classes, specifically `NamedParameterJdbcTemplate`. The template classes handle obtaining and releasing a connection for data access when one is needed.

The next example shows how to use `NamedParameterJdbcTemplate` inside of a DAO (Data Access Object) class to retrieve a random city given a country code.

```
public class Ex2JdbcDao {
    /**
     * Data source reference which will be provided by Spring.
     */
    private DataSource dataSource;

    /**
     * Our query to find a random city given a country code. Notice
     * the ":country" parameter toward the end. This is called a
     * named parameter.
     */
    private String queryString = "select Name from City " +
        "where CountryCode = :country order by rand() limit 1";

    /**
     * Retrieve a random city using Spring JDBC access classes.
     */
    public String getRandomCityByCountryCode(String cntryCode) {
        // A template that permits using queries with named parameters
        NamedParameterJdbcTemplate template =
            new NamedParameterJdbcTemplate(dataSource);
        // A java.util.Map is used to provide values for the parameters
        Map params = new HashMap();
        params.put("country", cntryCode);
        // We query for an Object and specify what class we are expecting
        return (String)template.queryForObject(queryString, params, String.class);
    }

    /**
     * A JavaBean setter-style method to allow Spring to inject the data source.
     * @param dataSource
     */
}
```

```

*/
public void setDataSource(DataSource dataSource) {
    this.dataSource = dataSource;
}
}

```

The focus in the above code is on the `getRandomCityByCountryCode()` method. We pass a country code and use the `NamedParameterJdbcTemplate` to query for a city. The country code is placed in a Map with the key "country", which is the parameter is named in the SQL query.

To access this code, you need to configure it with Spring by providing a reference to the data source.

```

<bean id="dao" class="code.Ex2JdbcDao">
    <property name="dataSource" ref="dataSource"/>
</bean>

```

At this point, we can just grab a reference to the DAO from Spring and call `getRandomCityByCountryCode()`.

```

// Create the application context
ApplicationContext ctx =
new ClassPathXmlApplicationContext("ex2appContext.xml");
// Obtain a reference to our DAO
Ex2JdbcDao dao = (Ex2JdbcDao) ctx.getBean("dao");

String countryCode = "USA";

// Find a few random cities in the US
for(int i = 0; i < 4; ++i)
    System.out.printf("A random city in %s is %s\n", countryCode,
        dao.getRandomCityByCountryCode(countryCode));

```

This example shows how to use Spring's JDBC classes to completely abstract away the use of traditional JDBC classes including `Connection` and `PreparedStatement`.

22.3.13.2. Transactional JDBC Access

You might be wondering how we can add transactions into our code if we do not deal directly with the JDBC classes. Spring provides a transaction management package that not only replaces JDBC transaction management, but also enables declarative transaction management (configuration instead of code).

To use transactional database access, we will need to change the storage engine of the tables in the world database. The downloaded script explicitly creates MyISAM tables which do not support transactional semantics. The InnoDB storage engine does support transactions and this is what we will be using. We can change the storage engine with the following statements.

```

ALTER TABLE City ENGINE=InnoDB;
ALTER TABLE Country ENGINE=InnoDB;
ALTER TABLE CountryLanguage ENGINE=InnoDB;

```

A good programming practice emphasized by Spring is separating interfaces and implementations. What this means is that we can create a Java interface and only use the operations on this interface without any internal knowledge of what the actual implementation is. We will let Spring manage the implementation and with this it will manage the transactions for our implementation.

First you create a simple interface:

```

public interface Ex3Dao {
    Integer createCity(String name, String countryCode,
        String district, Integer population);
}

```

This interface contains one method that will create a new city record in the database and return the id of the new record. Next you need to create an implementation of this interface.

```
public class Ex3DaoImpl implements Ex3Dao {
    protected DataSource dataSource;
    protected SqlUpdate updateQuery;
    protected SqlFunction idQuery;

    public Integer createCity(String name, String countryCode,
        String district, Integer population) {
        updateQuery.update(new Object[] { name, countryCode,
            district, population });
        return getLastId();
    }

    protected Integer getLastId() {
        return idQuery.run();
    }
}
```

You can see that we only operate on abstract query objects here and do not deal directly with the JDBC API. Also, this is the complete implementation. All of our transaction management will be dealt with in the configuration. To get the configuration started, we need to create the DAO.

```
<bean id="dao" class="code.Ex3DaoImpl">
    <property name="dataSource" ref="dataSource"/>
    <property name="updateQuery">...</property>
    <property name="idQuery">...</property>
</bean>
```

Now you need to set up the transaction configuration. The first thing you must do is create transaction manager to manage the data source and a specification of what transaction properties are required for the [dao](#) methods.

```
<bean id="transactionManager"
    class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
    <property name="dataSource" ref="dataSource"/>
</bean>

<tx:advice id="txAdvice" transaction-manager="transactionManager">
    <tx:attributes>
        <tx:method name="*" />
    </tx:attributes>
</tx:advice>
```

The preceding code creates a transaction manager that handles transactions for the data source provided to it. The [txAdvice](#) uses this transaction manager and the attributes specify to create a transaction for all methods. Finally you need to apply this advice with an AOP pointcut.

```
<aop:config>
    <aop:pointcut id="daoMethods"
        expression="execution(* code.Ex3Dao.*(..))"/>
    <aop:advisor advice-ref="txAdvice" pointcut-ref="daoMethods"/>
</aop:config>
```

This basically says that all methods called on the [Ex3Dao](#) interface will be wrapped in a transaction. To make use of this, you only have to retrieve the [dao](#) from the application context and call a method on the [dao](#) instance.

```
Ex3Dao dao = (Ex3Dao) ctx.getBean("dao");
Integer id = dao.createCity(name, countryCode, district, pop);
```

We can verify from this that there is no transaction management happening in our Java code and it is all configured with Spring. This is a very powerful notion and regarded as one of the most beneficial features of Spring.

22.3.13.3. Connection Pooling with Spring

In many situations, such as web applications, there will be a large number of small database transactions. When this is the case, it usually makes sense to create a pool of database connections available for web requests as needed. Although MySQL does not spawn an extra process when a connection is made, there is still a small amount of overhead to create and set up the connection. Pooling of connections also alleviates problems such as collecting large amounts of sockets in the `TIME_WAIT` state.

Setting up pooling of MySQL connections with Spring is as simple as changing the data source configuration in the application context. There are a number of configurations that we can use. The first example is based on the [Jakarta Commons DBCP library](#). The example below replaces the source configuration that was based on `DriverManagerDataSource` with DBCP's `BasicDataSource`.

```
<bean id="dataSource" destroy-method="close"
  class="org.apache.commons.dbcp.BasicDataSource">
  <property name="driverClassName" value="${db.driver}"/>
  <property name="url" value="${db.jdbcurl}"/>
  <property name="username" value="${db.username}"/>
  <property name="password" value="${db.password}"/>
  <property name="initialSize" value="3"/>
</bean>
```

The configuration of the two solutions is very similar. The difference is that DBCP will pool connections to the database instead of creating a new connection every time one is requested. We have also set a parameter here called `initialSize`. This tells DBCP that we want three connections in the pool when it is created.

Another way to configure connection pooling is to configure a data source in our J2EE application server. Using JBoss as an example, you can set up the MySQL connection pool by creating a file called `mysql-local-ds.xml` and placing it in the `server/default/deploy` directory in JBoss. Once we have this setup, we can use JNDI to look it up. With Spring, this lookup is very simple. The data source configuration looks like this.

```
<jee:jndi-lookup id="dataSource" jndi-name="java:MySQL_DS"/>
```

22.3.14. Using Connector/J with GlassFish

This section explains how to use MySQL Connector/J with Glassfish™ Server Open Source Edition 3.0.1. Glassfish can be downloaded from the [Glassfish website](#).

Once Glassfish is installed you will need to make sure it can access MySQL Connector/J. To do this copy the MySQL Connector/J JAR file to the directory `GLASSFISH_INSTALL/glassfish/lib`. For example, copy `mysql-connector-java-5.1.12-bin.jar` to `C:\glassfishv3\glassfish\lib`. Restart the Glassfish Application Server.

You are now ready to create JDBC Connection Pools and JDBC Resources.

Creating a Connection Pool

1. In the Glassfish Administration Console, using the navigation tree navigate to **Resources, JDBC, Connection Pools**.

2. In the **JDBC Connection Pools** frame click **New**. You will enter a two step wizard.
3. In the **Name** field under **General Settings** enter the name for the connection pool, for example enter [MySQLConnPool](#).
4. In the **Resource Type** field, select [javax.sql.DataSource](#) from the drop-down listbox.
5. In the **Database Vendor** field, select [MySQL](#) from the drop-down listbox. Click **Next** to go to the next page of the wizard.
6. You can accept the default settings for General Settings, Pool Settings and Transactions for this example. Scroll down to Additional Properties.
7. In Additional Properties you will need to ensure the following properties are set:
 - **ServerName** - The server to connect to. For local testing this will be [localhost](#).
 - **User** - The user name with which to connect to MySQL.
 - **Password** - The corresponding password for the user.
 - **DatabaseName** - The database to connect to, for example the sample MySQL database [World](#).
8. Click **Finish** to exit the wizard. You will be taken to the **JDBC Connection Pools** page where all current connection pools, including the one you just created, will be displayed.
9. In the **JDBC Connection Pools** frame click on the connection pool you just created. Here you can review and edit information about the connection pool.
10. To test your connection pool click the **Ping** button at the top of the frame. A message will be displayed confirming correct operation or otherwise. If an error message is received recheck the previous steps, and ensure that MySQL Connector/J has been correctly copied into the previously specified location.

Now that you have created a connection pool you will also need to create a JDBC Resource (data source) for use by your application.

Creating a JDBC Resource

Your Java application will usually reference a data source object to establish a connection with the database. This needs to be created first using the following procedure.

- Using the navigation tree in the Glassfish Administration Console, navigate to **Resources, JDBC, JDBC Resources**. A list of resources will be displayed in the **JDBC Resources** frame.
- Click **New**. The **New JDBC Resource** frame will be displayed.
- In the **JNDI Name** field, enter the JNDI name that will be used to access this resource, for example enter [jdbc/MySQLDataSource](#).
- In the **Pool Name** field, select a connection pool you want this resource to use from the drop-down listbox.
- Optionally, you can enter a description into the **Description** field.
- Additional properties can be added if required.
- Click **OK** to create the new JDBC resource. The **JDBC Resources** frame will list all available JDBC Resources.

22.3.14.1. A Simple JSP Application with Glassfish, Connector/J and MySQL

This section shows how to deploy a simple JSP application on Glassfish, that connects to a MySQL database.

This example assumes you have already set up a suitable Connection Pool and JDBC Resource, as explained in the preceding sections. It is also assumed you have a sample database installed, such as [world](#).

The main application code, [index.jsp](#) is presented here:

```
<%@ page import="java.sql.*, javax.sql.*, java.io.*, javax.naming.*" %>
<html>
<head><title>Hello world from JSP</title></head>
<body>
<%
    InitialContext ctx;
    DataSource ds;
    Connection conn;
    Statement stmt;
    ResultSet rs;

    try {
        ctx = new InitialContext();
        ds = (DataSource) ctx.lookup("java:comp/env/jdbc/MySQLDataSource");
        //ds = (DataSource) ctx.lookup("jdbc/MySQLDataSource");
        conn = ds.getConnection();
        stmt = conn.createStatement();
        rs = stmt.executeQuery("SELECT * FROM Country");

        while(rs.next()) {
%>
            <h3>Name: <%= rs.getString("Name") %></h3>
            <h3>Population: <%= rs.getString("Population") %></h3>
<%
        }
    }
    catch (SQLException se) {
%>
        <%= se.getMessage() %>
<%
    }
    catch (NamingException ne) {
%>
        <%= ne.getMessage() %>
<%
    }
%>
</body>
</html>
```

In addition two XML files are required: [web.xml](#), and [sun-web.xml](#). There may be other files present, such as classes and images. These files are organized into the directory structure as follows:

```
index.jsp
WEB-INF
|
- web.xml
- sun-web.xml
```

The code for [web.xml](#) is:

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
<web-app version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  <display-name>HelloWebApp</display-name>
  <distributable/>
  <resource-ref>
    <res-ref-name>jdbc/MySQLDataSource</res-ref-name>
    <res-type>javax.sql.DataSource</res-type>
    <res-auth>Container</res-auth>
    <res-sharing-scope>Shareable</res-sharing-scope>
  </resource-ref>
</web-app>
```

The code for `sun-web.xml` is:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE sun-web-app PUBLIC "-//Sun Microsystems, Inc.//DTD Application Server 8.1 Servlet 2.4//EN" "http://www.sun.com/xml/ns/sun-web-app"
<sun-web-app>
  <context-root>HelloWebApp</context-root>
  <resource-ref>
    <res-ref-name>jdbc/MySQLDataSource</res-ref-name>
    <jndi-name>jdbc/MySQLDataSource</jndi-name>
  </resource-ref>
</sun-web-app>
```

These XML files illustrate a very important aspect of running JDBC applications on Glassfish. On Glassfish it is important to map the string specified for a JDBC resource to its JNDI name, as set up in the Glassfish administration console. In this example, the JNDI name for the JDBC resource, as specified in the Glassfish Administration console when creating the JDBC Resource, was `jdbc/MySQLDataSource`. This must be mapped to the name given in the application. In this example the name specified in the application, `jdbc/MySQLDataSource`, and the JNDI name, happen to be the same, but this does not necessarily have to be the case. Note that the XML element `<res-ref-name>` is used to specify the name as used in the application source code, and this is mapped to the JNDI name specified using the `<jndi-name>` element, in the file `sun-web.xml`. The resource also has to be created in the `web.xml` file, although the mapping of the resource to a JNDI name takes place in the `sun-web.xml` file.

If you do not have this mapping set up correctly in the XML files you will not be able to lookup the data source using a JNDI lookup string such as:

```
ds = (DataSource) ctx.lookup("java:comp/env/jdbc/MySQLDataSource");
```

You will still be able to access the data source directly using:

```
ds = (DataSource) ctx.lookup("jdbc/MySQLDataSource");
```

With the source files in place, in the correct directory structure, you are ready to deploy the application:

1. In the navigation tree, navigate to **Applications** - the **Applications** frame will be displayed. Click **Deploy**.
2. You can now deploy an application packaged into a single WAR file from a remote client, or you can choose a packaged file or directory that is locally accessible to the server. If you are simply testing an application locally you can simply point Glassfish at the directory that contains your application, without needing to package the application into a WAR file.
3. Now select the application type from the **Type** drop-down listbox, which in this example is **Web application**.
4. Click OK.

Now, when you navigate to the **Applications** frame, you will have the option to **Launch**, **Redeploy**, or **Restart** your application. You can test your application by clicking **Launch**. The application will connect to the MySQL database and display the Name and Population of countries in the **Country** table.

22.3.14.2. A Simple Servlet with Glassfish, Connector/J and MySQL

This section describes a simple servlet that can be used in the Glassfish environment to access a MySQL database. As with the previous section, this example assumes the sample database `world` is installed.

The project is set up with the following directory structure:

```
index.html
WEB-INF
|
- web.xml
- sun-web.xml
- classes
  |
  - HelloWebServlet.java
  - HelloWebServlet.class
```

The code for the servlet, located in `HelloWebServlet.java`, is as follows:

```
import javax.servlet.http.*;
import javax.servlet.*;
import java.io.*;
import java.sql.*;
import javax.sql.*;
import javax.naming.*;

public class HelloWebServlet extends HttpServlet {

    InitialContext ctx = null;
    DataSource ds = null;
    Connection conn = null;
    PreparedStatement ps = null;
    ResultSet rs = null;

    String sql = "SELECT Name, Population FROM Country WHERE Name=?";

    public void init () throws ServletException {
        try {
            ctx = new InitialContext();
            ds = (DataSource) ctx.lookup("java:comp/env/jdbc/MySQLDataSource");
            conn = ds.getConnection();
            ps = conn.prepareStatement(sql);
        }
        catch (SQLException se) {
            System.out.println("SQLException: "+se.getMessage());
        }
        catch (NamingException ne){
            System.out.println("NamingException: "+ne.getMessage());
        }
    }

    public void destroy () {
        try {
            if (rs != null)
                rs.close();
            if (ps != null)
                ps.close();
            if (conn != null)
                conn.close();
            if (ctx != null)
                ctx.close();
        }
        catch (SQLException se) {
            System.out.println("SQLException: "+se.getMessage());
        }
    }
}
```

```

catch (NamingException ne) {
    System.out.println("NamingException: "+ne.getMessage());
}
}

public void doPost(HttpServletRequest req, HttpServletResponse resp){
    try {
        String country_name = req.getParameter("country_name");
        resp.setContentType("text/html");
        PrintWriter writer = resp.getWriter();
        writer.println("<html><body>");
        writer.println("<p>Country: "+country_name+"</p>");
        ps.setString(1, country_name);
        rs = ps.executeQuery();
        if (!rs.next()){
            writer.println("<p>Country does not exist!</p>");
        }
        else {
            rs.beforeFirst();
            while(rs.next()) {
                writer.println("<p>Name: "+rs.getString("Name")+"</p>");
                writer.println("<p>Population: "+rs.getString("Population")+"</p>");
            }
        }
        writer.println("</body></html>");
        writer.close();
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}

public void doGet(HttpServletRequest req, HttpServletResponse resp){
    try {
        resp.setContentType("text/html");
        PrintWriter writer = resp.getWriter();
        writer.println("<html><body>");
        writer.println("<p>Hello from servlet doGet()</p>");
        writer.println("</body></html>");
        writer.close();
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}
}

```

In the preceding code a basic `doGet()` method is implemented, but is not used in the example. The code to establish the connection with the database is as shown in the previous example, [Section 22.3.14.1, "A Simple JSP Application with Glassfish, Connector/J and MySQL"](#), and is most conveniently located in the servlet `init()` method. The corresponding freeing of resources is located in the destroy method. The main functionality of the servlet is located in the `doPost()` method. If the user enters into the input form a country name that can be located in the database, the population of the country is returned. The code is invoked using a POST action associated with the input form. The form is defined in the file [index.html](#):

```

<html>
  <head><title>HelloWebServlet</title></head>

  <body>
    <h1>HelloWebServlet</h1>

    <p>Please enter country name:</p>

    <form action="HelloWebServlet" method="POST">
      <input type="text" name="country_name" length="50" />

```

```
<input type="submit" value="Submit" />
</form>

</body>
</html>
```

The XML files `web.xml` and `sun-web.xml` are as for the example in the preceding section, [Section 22.3.14.1, “A Simple JSP Application with Glassfish, Connector/J and MySQL”](#), no additional changes are required.

When compiling the Java source code, you will need to specify the path to the file `javaee.jar`. On Windows, this can be done as follows:

```
shell> javac -classpath c:\glassfishv3\glassfish\lib\javaee.jar HelloWebServlet.java
```

Once the code is correctly located within its directory structure, and compiled, the application can be deployed in Glassfish. This is done in exactly the same way as described in the preceding section, [Section 22.3.14.1, “A Simple JSP Application with Glassfish, Connector/J and MySQL”](#).

Once deployed the application can be launched from within the Glassfish Administration Console. Enter a country name such as “England”, and the application will return “Country does not exist!”. Enter “France”, and the application will return a population of 59225700.

22.3.15. Troubleshooting Connector/J Applications

This section explains the symptoms and resolutions for the most commonly encountered issues with applications using MySQL Connector/J.

Questions

- [23.3.15.1: \[2976\]](#) When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What is going on? I can connect just fine with the MySQL command-line client.

- [23.3.15.2: \[2977\]](#) My application throws an SQLException 'No Suitable Driver'. Why is this happening?
- [23.3.15.3: \[2977\]](#) I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

- [23.3.15.4: \[2977\]](#) I have a servlet/application that works fine for a day, and then stops working overnight
- [23.3.15.5: \[2980\]](#) I'm trying to use JDBC 2.0 updatable result sets, and I get an exception saying my result set is not updatable.
- [23.3.15.6: \[2980\]](#) I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.

- [23.3.15.7: \[2980\]](#) I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```
java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

- [23.3.15.8: \[2980\]](#) My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting a error and stack trace, but these only occur after a fixed period of heavy activity.
- [23.3.15.9: \[2981\]](#) When using `gcj` an `java.io.CharConversionException` is raised when working with certain character sequences.
- [23.3.15.10: \[2981\]](#) Updating a table that contains a primary key that is either `FLOAT` or compound primary key that uses `FLOAT` fails to update the table and raises an exception.
- [23.3.15.11: \[2981\]](#) You get an `ER_NET_PACKET_TOO_LARGE [3989]` exception, even though the binary blob size you want to insert using JDBC is safely below the `max_allowed_packet [519]` size.
- [23.3.15.12: \[2981\]](#) What should you do if you receive error messages similar to the following: “Communications link failure – Last packet sent to the server was X ms ago”?
- [23.3.15.13: \[2982\]](#) Why does Connector/J not reconnect to MySQL and re-issue the statement after a communication failure, instead of throwing an Exception, even though I use the `autoReconnect` connection string option?
- [23.3.15.14: \[2983\]](#) How can I use 3-byte UTF8 with Connector/J?
- [23.3.15.15: \[2983\]](#) How can I use 4-byte UTF8, `utf8mb4` with Connector/J?
- [23.3.15.16: \[2983\]](#) Using `useServerPrepStmts=false` and certain character encodings can lead to corruption when inserting BLOBs. How can this be avoided?

Questions and Answers

23.3.15.1: When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What is going on? I can connect just fine with the MySQL command-line client.

MySQL Connector/J must use TCP/IP sockets to connect to MySQL, as Java does not support Unix Domain Sockets. Therefore, when MySQL Connector/J connects to MySQL, the security manager in MySQL server will use its grant tables to determine whether the connection is permitted.

You must add the necessary security credentials to the MySQL server for this to happen, using the `GRANT` statement to your MySQL Server. See [Section 13.7.1.3, “GRANT Syntax”](#), for more information.

Note

Testing your connectivity with the `mysql` command-line client will not work unless you add the "host" flag, and use something other than `localhost` for the host. The `mysql` command-line client will use Unix domain sockets if you use the special host name `localhost`. If you are testing connectivity to `localhost`, use `127.0.0.1` as the host name instead.

Warning

Changing privileges and permissions improperly in MySQL can potentially cause your server installation to not have optimal security properties.

23.3.15.2: My application throws an SQLException 'No Suitable Driver'. Why is this happening?

There are three possible causes for this error:

- The Connector/J driver is not in your `CLASSPATH`, see [Section 22.3.3, "Connector/J Installation"](#).
- The format of your connection URL is incorrect, or you are referencing the wrong JDBC driver.
- When using `DriverManager`, the `jdbc.drivers` system property has not been populated with the location of the Connector/J driver.

23.3.15.3: I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

Either you're running an Applet, your MySQL server has been installed with the "skip-networking" option set, or your MySQL server has a firewall sitting in front of it.

Applets can only make network connections back to the machine that runs the web server that served the .class files for the applet. This means that MySQL must run on the same machine (or you must have some sort of port re-direction) for this to work. This also means that you will not be able to test applets from your local file system, you must always deploy them to a web server.

MySQL Connector/J can only communicate with MySQL using TCP/IP, as Java does not support Unix domain sockets. TCP/IP communication with MySQL might be affected if MySQL was started with the "skip-networking" flag, or if it is firewalled.

If MySQL has been started with the "skip-networking" option set (the Debian Linux package of MySQL server does this for example), you need to comment it out in the file `/etc/mysql/my.cnf` or `/etc/my.cnf`. Of course your `my.cnf` file might also exist in the `data` directory of your MySQL server, or anywhere else (depending on how MySQL was compiled for your system). Binaries created by us always look in `/etc/my.cnf` and `[datadir]/my.cnf`. If your MySQL server has been firewalled, you will need to have the firewall configured to allow TCP/IP connections from the host where your Java code is running to the MySQL server on the port that MySQL is listening to (by default, 3306).

23.3.15.4: I have a servlet/application that works fine for a day, and then stops working overnight

MySQL closes connections after 8 hours of inactivity. You either need to use a connection pool that handles stale connections or use the "autoReconnect" parameter (see [Section 22.3.5.1, "Driver/ Datasource Class Names, URL Syntax and Configuration Properties for Connector/J"](#)).

Also, catch `SQLExceptions` in your application and deal with them, rather than propagating them all the way until your application exits. This is just good programming practice. MySQL Connector/J will set the `SQLState` (see `java.sql.SQLException.getSQLState()` in your API docs) to "08S01" when it encounters network-connectivity issues during the processing of a query. Attempt to reconnect to MySQL at this point.

The following (simplistic) example shows what code that can handle these exceptions might look like:

Example 22.12. Connector/J: Example of transaction with retry logic

```
public void doBusinessOp() throws SQLException {
    Connection conn = null;
    Statement stmt = null;
    ResultSet rs = null;

    //
    // How many times do you want to retry the transaction
    // (or at least _getting_ a connection)?
    //
    int retryCount = 5;

    boolean transactionCompleted = false;

    do {
        try {
            conn = getConnection(); // assume getting this from a
                                   // javax.sql.DataSource, or the
                                   // java.sql.DriverManager

            conn.setAutoCommit(false);

            //
            // Okay, at this point, the 'retry-ability' of the
            // transaction really depends on your application logic,
            // whether or not you're using autocommit (in this case
            // not), and whether you're using transactional storage
            // engines
            //
            // For this example, we'll assume that it's _not_ safe
            // to retry the entire transaction, so we set retry
            // count to 0 at this point
            //
            // If you were using exclusively transaction-safe tables,
            // or your application could recover from a connection going
            // bad in the middle of an operation, then you would not
            // touch 'retryCount' here, and just let the loop repeat
            // until retryCount == 0.
            //
            retryCount = 0;

            stmt = conn.createStatement();

            String query = "SELECT foo FROM bar ORDER BY baz";

            rs = stmt.executeQuery(query);

            while (rs.next()) {
            }

            rs.close();
            rs = null;

            stmt.close();
            stmt = null;

            conn.commit();
        }
    }
}
```

```

        conn.close();
        conn = null;

        transactionCompleted = true;
    } catch (SQLException sqlEx) {

        //
        // The two SQL states that are 'retry-able' are 08S01
        // for a communications error, and 40001 for deadlock.
        //
        // Only retry if the error was due to a stale connection,
        // communications problem or deadlock
        //
        String sqlState = sqlEx.getSQLState();

        if ("08S01".equals(sqlState) || "40001".equals(sqlState)) {
            retryCount -= 1;
        } else {
            retryCount = 0;
        }
    } finally {
        if (rs != null) {
            try {
                rs.close();
            } catch (SQLException sqlEx) {
                // You'd probably want to log this...
            }
        }

        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException sqlEx) {
                // You'd probably want to log this as well...
            }
        }

        if (conn != null) {
            try {
                //
                // If we got here, and conn is not null, the
                // transaction should be rolled back, as not
                // all work has been done

                try {
                    conn.rollback();
                } finally {
                    conn.close();
                }
            } catch (SQLException sqlEx) {
                //
                // If we got an exception here, something
                // pretty serious is going on, so we better
                // pass it up the stack, rather than just
                // logging it...

                throw sqlEx;
            }
        }
    }
} while (!transactionCompleted && (retryCount > 0));
}

```

Note

Use of the `autoReconnect` option is not recommended because there is no safe method of reconnecting to the MySQL server without risking some corruption of the connection state or database state information. Instead, use a connection pool, which will enable your application to connect to the MySQL server using an available connection from the pool. The `autoReconnect` facility is deprecated, and may be removed in a future release.

23.3.15.5: I'm trying to use JDBC 2.0 updatable result sets, and I get an exception saying my result set is not updatable.

Because MySQL does not have row identifiers, MySQL Connector/J can only update result sets that have come from queries on tables that have at least one primary key, the query must select every primary key and the query can only span one table (that is, no joins). This is outlined in the JDBC specification.

Note that this issue only occurs when using updatable result sets, and is caused because Connector/J is unable to guarantee that it can identify the correct rows within the result set to be updated without having a unique reference to each row. There is no requirement to have a unique field on a table if you are using `UPDATE` or `DELETE` statements on a table where you can individually specify the criteria to be matched using a `WHERE` clause.

23.3.15.6: I cannot connect to the MySQL server using Connector/J, and I'm sure the connection parameters are correct.

Make sure that the `skip-networking` [461] option has not been enabled on your server. Connector/J must be able to communicate with your server over TCP/IP, named sockets are not supported. Also ensure that you are not filtering connections through a Firewall or other network security system. For more information, see [Section C.5.2.2, "Can't connect to \[local\] MySQL server"](#).

23.3.15.7: I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```
java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

The error probably indicates that you are using a older version of the Connector/J JDBC driver (2.0.14 or 3.0.x) and you are trying to connect to a MySQL server with version 4.1x or newer. The older drivers are not compatible with 4.1 or newer of MySQL as they do not support the newer authentication mechanisms.

It is likely that the older version of the Connector/J driver exists within your application directory or your `CLASSPATH` includes the older Connector/J package.

23.3.15.8: My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting a error and stack trace, but these only occur after a fixed period of heavy activity.

This is a JBoss, not Connector/J, issue and is connected to the use of transactions. Under heavy loads the time taken for transactions to complete can increase, and the error is caused because you have exceeded the predefined timeout.

You can increase the timeout value by setting the `TransactionTimeout` attribute to the `TransactionManagerService` within the `/conf/jboss-service.xml` file (pre-4.0.3) or `/deploy/jta-service.xml` for JBoss 4.0.3 or later. See `TransactionTimeout` within the JBoss wiki for more information.

23.3.15.9: When using `gcj` an `java.io.CharConversionException` is raised when working with certain character sequences.

This is a known issue with `gcj` which raises an exception when it reaches an unknown character or one it cannot convert. Add `useJvmCharsetConverters=true` to your connection string to force character conversion outside of the `gcj` libraries, or try a different JDK.

23.3.15.10: Updating a table that contains a primary key that is either `FLOAT` or compound primary key that uses `FLOAT` fails to update the table and raises an exception.

Connector/J adds conditions to the `WHERE` clause during an `UPDATE` to check the old values of the primary key. If there is no match then Connector/J considers this a failure condition and raises an exception.

The problem is that rounding differences between supplied values and the values stored in the database may mean that the values never match, and hence the update fails. The issue will affect all queries, not just those from Connector/J.

To prevent this issue, use a primary key that does not use `FLOAT`. If you have to use a floating point column in your primary key use `DOUBLE` or `DECIMAL` types in place of `FLOAT`.

23.3.15.11: You get an `ER_NET_PACKET_TOO_LARGE [3989]` exception, even though the binary blob size you want to insert using JDBC is safely below the `max_allowed_packet [519]` size.

This is because the `hexEscapeBlock()` method in `com.mysql.jdbc.PreparedStatement.streamToBytes()` may almost double the size of your data.

23.3.15.12: What should you do if you receive error messages similar to the following: “Communications link failure – Last packet sent to the server was X ms ago”?

Generally speaking, this error suggests that the network connection has been closed. There can be several root causes:

- Firewalls or routers may clamp down on idle connections (the MySQL client/server protocol does not ping).
- The MySQL Server may be closing idle connections which exceed the `wait_timeout` or `interactive_timeout` threshold.

To help troubleshoot these issues, the following tips can be used. If a recent (5.1.13+) version of Connector/J is used, you will see an improved level of information compared to earlier versions. Older versions simply display the last time a packet was sent to the server, which is frequently 0 ms ago. This is of limited use, as it may be that a packet was just sent, while a packet from the server has not been received for several hours. Knowing the period of time since Connector/J last received a packet from the server is useful information, so if this is not displayed in your exception message, it is recommended that you update Connector/J.

Further, if the time a packet was last sent/received exceeds the `wait_timeout` or `interactive_timeout` threshold, this is noted in the exception message.

Although network connections can be volatile, the following can be helpful in avoiding problems:

- Ensure connections are valid when used from the connection pool. Use a query that starts with `/* ping */` to execute a lightweight ping instead of full query. Note, the syntax of the ping needs to be exactly as specified here.
- Minimize the duration a connection object is left idle while other application logic is executed.
- Explicitly validate the connection before using it if the connection has been left idle for an extended period of time.
- Ensure that `wait_timeout` and `interactive_timeout` are set sufficiently high.
- Ensure that `tcpKeepalive` is enabled.
- Ensure that any configurable firewall or router timeout settings allow for the maximum expected connection idle time.

Note

Do not expect to be able to reuse a connection without problems, if it has been lying idle for a period. If a connection is to be reused after being idle for any length of time, ensure that you explicitly test it before reusing it.

23.3.15.13: Why does Connector/J not reconnect to MySQL and re-issue the statement after a communication failure, instead of throwing an Exception, even though I use the `autoReconnect` connection string option?

There are several reasons for this. The first is transactional integrity. The MySQL Reference Manual states that “there is no safe method of reconnecting to the MySQL server without risking some corruption of the connection state or database state information”. Consider the following series of statements for example:

```
conn.createStatement().execute(
    "UPDATE checking_account SET balance = balance - 1000.00 WHERE customer='Smith'");
conn.createStatement().execute(
    "UPDATE savings_account SET balance = balance + 1000.00 WHERE customer='Smith'");
conn.commit();
```

Consider the case where the connection to the server fails after the `UPDATE` to `checking_account`. If no exception is thrown, and the application never learns about the problem, it will continue executing. However, the server did not commit the first transaction in this case, so that will get rolled back. But execution continues with the next transaction, and increases the `savings_account` balance by 1000. The application did not receive an exception, so it continued regardless, eventually committing the second transaction, as the commit only applies to the changes made in the new connection. Rather than a transfer taking place, a deposit was made in this example.

Note that running with `auto-commit` enabled does not solve this problem. When Connector/J encounters a communication problem, there is no means to determine whether the server processed the currently executing statement or not. The following theoretical states are equally possible:

- The server never received the statement, and therefore no related processing occurred on the server.
- The server received the statement, executed it in full, but the response was not received by the client.

If you are running with `auto-commit` enabled, it is not possible to guarantee the state of data on the server when a communication exception is encountered. The statement may have reached the server, or it may not. All you know is that communication failed at some point, before the client received confirmation

(or data) from the server. This does not only affect `auto-commit` statements though. If the communication problem occurred during `Connection.commit()`, the question arises of whether the transaction was committed on the server before the communication failed, or whether the server received the commit request at all.

The second reason for the generation of exceptions is that transaction-scoped contextual data may be vulnerable, for example:

- Temporary tables.
- User-defined variables.
- Server-side prepared statements.

These items are lost when a connection fails, and if the connection silently reconnects without generating an exception, this could be detrimental to the correct execution of your application.

In summary, communication errors generate conditions that may well be unsafe for Connector/J to simply ignore by silently reconnecting. It is necessary for the application to be notified. It is then for the application developer to decide how to proceed in the event of connection errors and failures.

23.3.15.14: How can I use 3-byte UTF8 with Connector/J?

To use 3-byte UTF8 with Connector/J set `characterEncoding=utf8` and set `useUnicode=true` in the connection string.

23.3.15.15: How can I use 4-byte UTF8, `utf8mb4` with Connector/J?

To use 4-byte UTF8 with Connector/J configure the MySQL server with `character_set_server=utf8mb4`. Connector/J will then use that setting as long as `characterEncoding` has not been set in the connection string. This is equivalent to autodetection of the character set.

23.3.15.16: Using `useServerPrepStmts=false` and certain character encodings can lead to corruption when inserting BLOBs. How can this be avoided?

When using certain character encodings, such as SJIS, CP932, and BIG5, it is possible that BLOB data contains characters that can be interpreted as control characters, for example, backslash, `\`. This can lead to corrupted data when inserting BLOBs into the database. There are two things that need to be done to avoid this:

1. Set the connection string option `useServerPrepStmts` to `true`.
2. Set `SQL_MODE` to `NO_BACKSLASH_ESCAPES`.

22.3.16. Connector/J Support

22.3.16.1. Connector/J Community Support

Oracle provides assistance to the user community by means of its mailing lists. For Connector/J related issues, you can get help from experienced users by using the MySQL and Java mailing list. Archives and subscription information is available online at <http://lists.mysql.com/java>.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See [Section 1.6.1, "MySQL Mailing Lists"](#).

Community support from experienced users is also available through the [JDBC Forum](#). You may also find help from other users in the other MySQL Forums, located at <http://forums.mysql.com>. See [Section 1.6.2, "MySQL Community Support at the MySQL Forums"](#).

22.3.16.2. How to Report Connector/J Bugs or Problems

The normal place to report bugs is <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you will also be able to enter new reports.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support at <http://support.oracle.com/>.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release.

This section will help you write your report correctly so that you do not waste your time doing things that may not help us much or at all.

If you have a repeatable bug report, please report it to the bugs database at <http://bugs.mysql.com/>. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter.

A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of Connector/J or MySQL used, and (b) not fully describing the platform on which Connector/J is installed (including the JVM version, and the platform type and version number that MySQL itself is installed on).

This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, "Why doesn't this work for me?" Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has already been fixed in newer MySQL versions.

Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If at all possible, create a repeatable, standalone testcase that doesn't involve any third-party classes.

To streamline this process, we ship a base class for testcases with Connector/J, named `'com.mysql.jdbc.util.BaseBugReport'`. To create a testcase for Connector/J using this class, create your own class that inherits from `com.mysql.jdbc.util.BaseBugReport` and override the methods `setUp()`, `tearDown()` and `runTest()`.

In the `setUp()` method, create code that creates your tables, and populates them with any data needed to demonstrate the bug.

In the `runTest()` method, create code that demonstrates the bug using the tables and data you created in the `setUp` method.

In the `tearDown()` method, drop any tables you created in the `setUp()` method.

In any of the above three methods, use one of the variants of the `getConnection()` method to create a JDBC connection to MySQL:

- `getConnection()` - Provides a connection to the JDBC URL specified in `getUrl()`. If a connection already exists, that connection is returned, otherwise a new connection is created.
- `getNewConnection()` - Use this if you need to get a new connection for your bug report (that is, there is more than one connection involved).
- `getConnection(String url)` - Returns a connection using the given URL.
- `getConnection(String url, Properties props)` - Returns a connection using the given URL and properties.

If you need to use a JDBC URL that is different from 'jdbc:mysql://test', override the method `getUrl()` as well.

Use the `assertTrue(boolean expression)` and `assertTrue(String failureMessage, boolean expression)` methods to create conditions that must be met in your testcase demonstrating the behavior you are expecting (vs. the behavior you are observing, which is why you are most likely filing a bug report).

Finally, create a `main()` method that creates a new instance of your testcase, and calls the `run` method:

```
public static void main(String[] args) throws Exception {
    new MyBugReport().run();
}
```

Once you have finished your testcase, and have verified that it demonstrates the bug you are reporting, upload it with your bug report to <http://bugs.mysql.com/>.

22.4. MySQL Connector/C++

MySQL Connector/C++ is a MySQL database connector for C++. It lets you develop applications in C++ that connect to the MySQL Server.

MySQL Connector/C++ Benefits

Using MySQL Connector/C++ instead of the MySQL C API (MySQL Client Library) offers the following benefits for C++ users:

- Convenience of pure C++, no C function calls required.
- Supports an industry standard API, JDBC 4.0.
- Supports the object-oriented programming paradigm.
- Reduces development time.
- MySQL Connector/C++ is licensed under the GPL with the FLOSS License Exception.
- MySQL Connector/C++ is available under a commercial license upon request.

JDBC Compatibility

The MySQL Connector/C++ is compatible with the JDBC 4.0 API. However, MySQL Connector/C++ does not implement all of the JDBC 4.0 API. The MySQL Connector/C++ current version features the following classes:

- `Connection`
- `DatabaseMetaData`
- `Driver`
- `PreparedStatement`
- `ResultSet`
- `ResultSetMetaData`
- `Savepoint`
- `Statement`

The JDBC 4.0 API defines approximately 450 methods for the above mentioned classes. MySQL Connector/C++ implements around 80% of these and makes them available in the current release.

Platform Support and Prerequisites

MySQL Connector/C++ supports MySQL 5.1 and later.

MySQL Connector/C++ supports only Microsoft Visual Studio 2003 and above on Windows.

The release has been successfully compiled and tested on the following platforms:

AIX

- 5.2 (PPC32, PPC64)
- 5.3 (PPC32, PPC64)

FreeBSD

- 6.0 (x86, x86_64)

HPUX

- 11.11 (PA-RISC 32bit, PA-RISC 64bit)

Linux

- Debian 3.1 (PPC32, x86)
- FC4 (x86)
- RHEL 3 (ia64, x86, x86_64)
- RHEL 4 (ia64, x86, x86_64)
- RHEL 5 (ia64, x86, x86_64)
- SLES 9 (ia64, x86, x86_64)

- SLES 10 (ia64, x86_64)
- SuSE 10.3, (x86_64)
- Ubuntu 8.04 (x86)
- Ubuntu 8.10 (x86_64)

Mac

- MacOSX 10.3 (PPC32, PPC64)
- MacOSX 10.4 (PPC32, PPC64, x86)
- MacOSX 10.5 (PPC32, PPC64, x86, x86_64)

SunOS

- Solaris 8 (SPARC32, SPARC64, x86)
- Solaris 9 (SPARC32, SPARC64, x86)
- Solaris 10 (SPARC32, SPARC64, x86, x86_64)

Windows

- XP Professional (32bit)
- 2003 (64bit)

Future versions will run on all platforms supported by the MySQL Server.

How to Get Connector/C++

MySQL Connector/C++ Download

You can download the source code for the MySQL Connector/C++ current release at the [MySQL Connector/C++ downloads](#).

MySQL Connector/C++ Source repository

The latest development version is also available through [Launchpad](#).

Bazaar is used for the MySQL Connector/C++ code repository. You can check out the latest source code using the [bzzr](#) command line tool:

```
shell> bzzr branch lp:~mysql/mysql-connector-cpp/trunk .
```

Binary distributions

Starting with 1.0.4 Beta, binary distributions were made available in addition to source code releases. The releases available are shown below.

Microsoft Windows platform:

- Without installer, a Zip file
- MSI installer package

Other platforms:

- Compressed GNU TAR archive (tar.gz)

**Note**

Note that source packages are available for all platforms in the Compressed GNU TAR archive (tar.gz) format.

Binary and source packages can be obtained from [MySQL Connector/C++ downloads](#).

Release Status

MySQL Connector/C++ is available as a GA version. We kindly ask users and developers to try it out and provide us with feedback.

Note that MySQL Workbench is successfully using MySQL Connector/C++.

If you have any queries please [contact us](#).

Licensing

The MySQL Connector/C++ is licensed under the terms of the GPL, like most MySQL Connectors. There are special exceptions to the terms and conditions of the GPL as it is applied to this software, see FLOSS License Exception. If you need a non-GPL license for commercial distribution, please contact us.

22.4.1. Installing the MySQL Connector/C++ Binary

**Caution**

One problem that can occur is when the tools you use to build your application are not compatible with the tools used to build the binary versions of MySQL Connector/C++. Ideally, build your application with the same tools that were used to build the MySQL Connector/C++ binaries. To help with this, the following resources are provided.

All distributions contain a [README](#) file, which contains platform-specific notes. At the end of the [README](#) file contained in the binary distribution you will find the settings used to build the binaries. If you experience build-related issues on a platform, it may help to check the settings used on the platform to build the binary.

Developers using Microsoft Windows must meet the following requirements:

1. Use a supported version of Visual Studio, either Visual Studio 2005 or Visual Studio 2008.
2. Ensure that your application uses the same run time library as that used to build MySQL Connector/C++. Visual Studio 2005 builds use Microsoft.VC80.CRT (8.0.50727.762), and Visual Studio 2008 builds use Microsoft.VC90.CRT (9.0.21022.8).
3. Your application should use the same linker configuration as MySQL Connector/C++, for example use one of `/MD`, `/MDd`, `/MT`, or `/MTd`.

To use a variation of the requirements previously listed, such as a different compiler version, release configuration, or run time library, compile MySQL Connector/C++ from source using your desired settings, and then ensure that your application is

built with these same settings. Ensure that the three variables of compiler version, run time library, and run time linker configuration settings are the same for both application and MySQL Connector/C++ itself, to avoid issues.

A better solution is to build your MySQL Connector/C++ libraries from the source code, using the same tools that you use for building your application. This ensures compatibility.

Downloading MySQL Connector/C++

Binary and source packages can be obtained from [MySQL Connector/C++ downloads](#).

Archive Package

Unpack the archive into an appropriate directory. If you plan to use a dynamically linked version of MySQL Connector/C++, make sure that your system can reference the MySQL Client Library. Consult your operating system documentation on how to modify and expand the search path for libraries. In case you cannot modify the library search path it may help to copy your application, the MySQL Connector/C++ library and the MySQL Client Library into the same directory. Most systems search for libraries in the current directory.

Windows MSI Installer

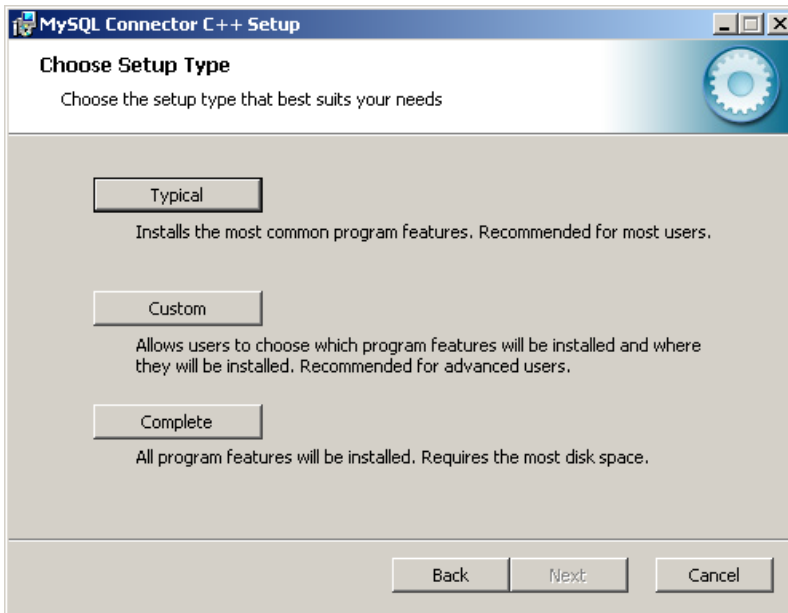

Windows users can choose between two binary packages:

1. Without installer (unzip in C:\)
2. Windows MSI Installer (x86)

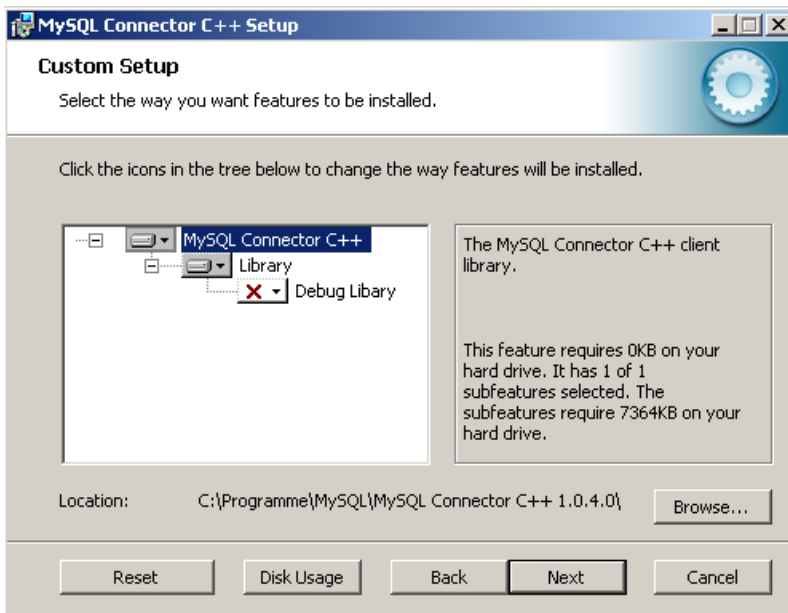

Using the MSI Installer may be the easiest solution. Running the MSI Installer does not require any administrative permissions as it simply copies files.

Figure 22.70. Windows Installer Welcome Screen

Figure 22.71. Windows Installer Overview Screen

The “Typical” installation consists of all required header files and the Release libraries. The only available “Custom” installation option enables you to install additional Debug versions of the connector libraries.

Figure 22.72. Windows Installer Custom Setup Screen

22.4.2. Installing MySQL Connector/C++ from Source

The MySQL Connector/C++ is based on the MySQL Client Library (MySQL C API). MySQL Connector/C++ is linked against the MySQL Client Library. You need the MySQL Client Library installed to compile MySQL Connector/C++.

You also need the cross-platform build tool [CMake](#) 2.4, or newer, and GLib 2.2.3 or newer installed. Check the [README](#) file included with the distribution for platform specific notes on building for Windows and SunOS.

Typically the MySQL Client Library is installed when the MySQL Server is installed. However, check your operating system documentation for other installation options.

As of MySQL Connector/C++ version 1.1.0, it is necessary to have the Boost C++ libraries 1.34.0 or newer installed. Boost is only required to build the connector, it is not required to use the connector. You can obtain Boost and its installation instructions from [the official site](#). Once Boost is installed, tell the make system where the Boost files are, by setting the define `-DBOOST_ROOT:STRING=`. This can be done when initially invoking [CMake](#), for example:

```
shell> CMake . -DBOOST_ROOT:STRING=/usr/local/boost_1_40_0
```

You might need to change `/usr/local/boost_1_40_0/` to match your installation. See the [Section 22.4.2.1, "Building MySQL Connector/C++ from Source on Unix, Solaris and Mac OS X"](#) and [Section 22.4.2.2, "Building MySQL Connector/C++ from Source on Windows"](#) for further details.

22.4.2.1. Building MySQL Connector/C++ from Source on Unix, Solaris and Mac OS X

1. Run [CMake](#) to build a [Makefile](#):

```
shell> me@host:/path/to/mysql-connector-cpp> cmake .
-- Check for working C compiler: /usr/local/bin/gcc
-- Check for working C compiler: /usr/local/bin/gcc -- works
[...]
-- Generating done
-- Build files have been written to: /path/to/mysql-connector-cpp/
```

On non-Windows systems, [CMake](#) first checks to see if the [CMake](#) variable `MYSQL_CONFIG_EXECUTABLE` is set. If it is not found [CMake](#) tries to locate `mysql_config` in the default locations.

If you have any problems with the configure process please check the troubleshooting instructions below.

2. Use `make` to build the libraries. First make sure you have a clean build:

```
shell> me@host:/path/to/mysql-connector-cpp> make clean
```

Then build the connector:

```
me@host:/path/to/mysql-connector-cpp> make
[ 1%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_connection.o
[ 3%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_constructed_resultset.o
[...]
[100%] Building CXX object examples/CMakeFiles/statement.dir/statement.o
Linking CXX executable statement
```

If all goes well, you will find the MySQL Connector/C++ library in `/path/to/cppconn/libmysqlcppconn.so`.

3. Finally make sure the header and library files are installed to their correct locations:

```
make install
```

Unless you have changed this in the configuration step, the header files are copied to the directory `/usr/local/include`. The header files copied are `mysql_connection.h` and `mysql_driver.h`.

Again, unless you have specified otherwise, the library files are copied to `/usr/local/lib`. The files copied are `libmysqlcppconn.so`, the dynamic library, and `libmysqlcppconn-static.a`, the static library.

If you encounter any errors, please first carry out the checks shown below:

1. **CMake** options: MySQL installation path, debug version and more

In case of configuration or compilation problems, check the list of **CMake** options:

```
shell> me@host:/path/to/mysql-connector-cpp> cmake -L
[...]
CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
CMAKE_BUILD_TYPE:STRING=
CMAKE_INSTALL_PREFIX:PATH=/usr/local
EXECUTABLE_OUTPUT_PATH:PATH=
LIBRARY_OUTPUT_PATH:PATH=
MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
MYSQL_CONFIG_EXECUTABLE:FILEPATH=/usr/bin/mysql_config
```

For example, if your MySQL Server installation path is not `/usr/local/mysql` and you want to build a debug version of the MySQL Connector/C++, use:

```
shell> me@host:/path/to/mysql-connector-cpp> cmake »
-D CMAKE_BUILD_TYPE:STRING=Debug »
-D MYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config .
```

2. Verify your settings with `cmake -L`:

```
shell> me@host:/path/to/mysql-connector-cpp> cmake -L
[...]
CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
CMAKE_BUILD_TYPE:STRING=
CMAKE_INSTALL_PREFIX:PATH=/usr/local
EXECUTABLE_OUTPUT_PATH:PATH=
LIBRARY_OUTPUT_PATH:PATH=
MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
MYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config
```

Proceed by carrying out a `make clean` command followed by a `make` command, as described above.

Once you have installed MySQL Connector/C++ you can carry out a quick test to check the installation. To do this you can compile and run one of the example programs, such as [examples/standalone_example.cpp](#). This example is discussed in more detail later, but for now you can use it to test the connector has been correctly installed. This procedure assumes you have a working MySQL Server that you can connect to.

1. First compile the example. To do this change to the `examples` directory and type:

```
shell> g++ -o test_install -I/usr/local/include -I/usr/local/include/cppconn -Wl,-Bdynamic -lmysqlcppconn s
```

2. Make sure the dynamic library which is used in this case can be found at runtime:

```
shell> export LD_LIBRARY_PATH=/usr/local/lib
```

3. Now run the program to test your installation, substituting the appropriate host, user, password and database names for your system:

```
./test_install localhost root password database
```

You will see something similar to the following:

```
Connector/C++ standalone program example...

... running 'SELECT 'Welcome to Connector/C++' AS _message'
... MySQL replies: Welcome to Connector/C++
... say it again, MySQL
...MySQL replies: Welcome to Connector/C++

... find more at http://www.mysql.com
```

If you see any errors, take note of them and go through the troubleshooting procedures discussed earlier.

22.4.2.2. Building MySQL Connector/C++ from Source on Windows

Note

Please note the only compiler formally supported for Windows is Microsoft Visual Studio 2003 and above.

The basic steps for building the connector on Windows are the same as for Unix. It is important to use [CMake](#) 2.6.2 or newer to generate build files for your compiler and to invoke the compiler.

Note

On Windows, `mysql_config` is not present, so [CMake](#) will attempt to retrieve the location of MySQL from the environment variable `$ENV{MYSQL_DIR}`. If `MYSQL_DIR` is not set, [CMake](#) will then proceed to check for MySQL in the following locations: `$ENV{ProgramFiles}/MySQL/*/include`, and `$ENV{SystemDrive}/MySQL/*/include`.

[CMake](#) makes it easy for you to try other compilers. However, you may experience compile warnings, compile errors or linking issues not detected by Visual Studio. Patches are gratefully accepted to fix issues with other compilers.

Consult the [CMake](#) manual or check `cmake --help` to find out which build systems are supported by your [CMake](#) version:

```
C:\>cmake --help
cmake version 2.6-patch 2
Usage
[...]
Generators

The following generators are available on this platform:
  Borland Makefiles      = Generates Borland makefiles.
  MSYS Makefiles         = Generates MSYS makefiles.
  MinGW Makefiles        = Generates a make file for use with
                          mingw32-make.
  NMake Makefiles        = Generates NMake makefiles.
  Unix Makefiles          = Generates standard UNIX makefiles.
  Visual Studio 6         = Generates Visual Studio 6 project files.
  Visual Studio 7         = Generates Visual Studio .NET 2002 project
                          files.
  Visual Studio 7 .NET 2003 = Generates Visual Studio .NET 2003 project
                          files.
  Visual Studio 8 2005    = Generates Visual Studio .NET 2005 project
                          files.
  Visual Studio 8 2005 Win64 = Generates Visual Studio .NET 2005 Win64
                          project files.
```

Installing MySQL Connector/C++ from Source

```
Visual Studio 9 2008      = Generates Visual Studio 9 2008 project fil
Visual Studio 9 2008 Win64 = Generates Visual Studio 9 2008 Win64 proje
                           files.
[...]
```

It is likely that your [CMake](#) binary will support more compilers, known by [CMake](#) as *generators*, than supported by MySQL Connector/C++. We have built the connector using the following generators:

- Microsoft Visual Studio 8 (Visual Studio 2005)
- Microsoft Visual Studio 9 (Visual Studio 2008, Visual Studio 2008 Express)
- NMake

Please see the building instructions for Unix, Solaris and Mac OS X for troubleshooting and configuration hints.

The steps to build the connector are given below:

1. Run [CMake](#) to generate build files for your *generator*.

Visual Studio

```
C:\path_to_mysql_cpp>cmake -G "Visual Studio 9 2008"
-- Check for working C compiler: cl
-- Check for working C compiler: cl -- works

| 19.11.2008 | 12:16 | 28.073 | PACKAGE.vcproj |
| 19.11.2008 | 12:16 | 27.495 | ZERO_CHECK.vcproj |

NMake

```
C:\path_to_mysql_cpp>cmake -G "NMake Makefiles"
-- The C compiler identification is MSVC
-- The CXX compiler identification is MSVC
[...]
-- Build files have been written to: C:\path_to_mysql_cpp
```

2. Use your compiler to build MySQL Connector/C++

Visual Studio - GUI

Open the newly generated project files in the Visual Studio GUI or use a Visual Studio command line to build the driver. The project files contain a variety of different configurations. Among them debug and nondebug versions.

Visual Studio - NMake

```
C:\path_to_mysql_cpp>nmake

Microsoft (R) Program Maintenance Utility Version 9.00.30729.01
Copyright (C) Microsoft Corporation. All rights reserved.

Scanning dependencies of target mysqlcppconn
[ 2%] Building CXX object driver/CMakeFiles/mysqlcppconn.dir/mysql_connection.obj
mysql_connection.cpp
[...]
Linking CXX executable statement.exe
[100%] Built target statement
```

22.4.2.3. Dynamically Linking MySQL Connector/C++ against the MySQL Client Library

Note

Note this section refers to dynamic linking of the MySQL Connector/C++ with the client library, not the dynamic linking of the application to MySQL Connector/C++.

An application that uses MySQL Connector/C++ can be either statically or dynamically linked to the MySQL Connector/C++ libraries. MySQL Connector/C++ is usually statically linked to the underlying MySQL Client Library (or Connector/C). Note, that unless otherwise stated, reference to the MySQL Client Library is also taken to include Connector/C, which is a separately packaged, stand alone version of the MySQL Client Library. From MySQL Connector/C++ version 1.1.0 it is possible to also dynamically link to the underlying MySQL Client Library. The ability of MySQL Connector/C++ to dynamically link to MySQL Client Library is not enabled by default, and enabling this feature is done through a compile time option, when compiling the MySQL Connector/C++ source code.

To use the ability to dynamically link the client library to MySQL Connector/C++, define the `MYSQLCLIENT_STATIC_BINDING:BOOL` when building the MySQL Connector/C++ source code:

```
rm CMakeCache.txt
cmake -DMYSQLCLIENT_STATIC_BINDING:BOOL=1 .
make clean
make
make install
```

Note that precompiled binaries of MySQL Connector/C++ use static binding with the client library by default.

Now, in your application, when creating a connection, MySQL Connector/C++ will select and load a client library at runtime. It will choose the client library by searching defined locations and environment variables depending on the host operating system. It is also possible when creating a connection in an application to define an absolute path to the client library to be loaded at runtime. This can be convenient if you have

defined a standard location from which you want the client library to be loaded. This is sometimes done to circumvent possible conflicts with other versions of the client library that may be located on the system.

22.4.3. MySQL Connector/C++ Building Windows Applications with Microsoft Visual Studio

MySQL Connector/C++ is available as a static or dynamic library to use with your application. This section looks at how to link the library to your application.

Note

To avoid potential crashes the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

Static library

The MySQL Connector/C++ static library file is `mysqlcppconn-static.lib`. You link this library statically with your application. Also link against the files `libmysql.dll` and `libmysql.lib`. Once linking has been successfully completed, the application will require access to `libmysql.dll` at run time.

Dynamic library

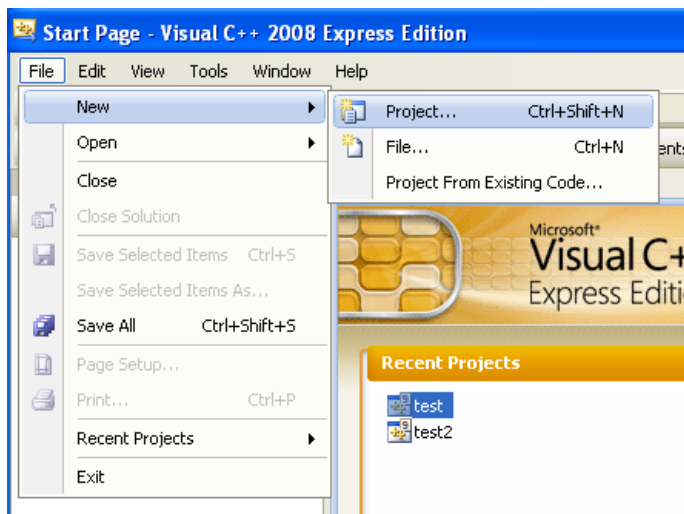

The MySQL Connector/C++ dynamic library file is `mysqlcppconn.dll`. To build your client application, link it with the file `mysqlcppconn.lib`. At run time, the application will require access to the files `mysqlcppconn.dll` and `libmysql.dll`.

Building a MySQL Connector/C++ application with Microsoft Visual Studio

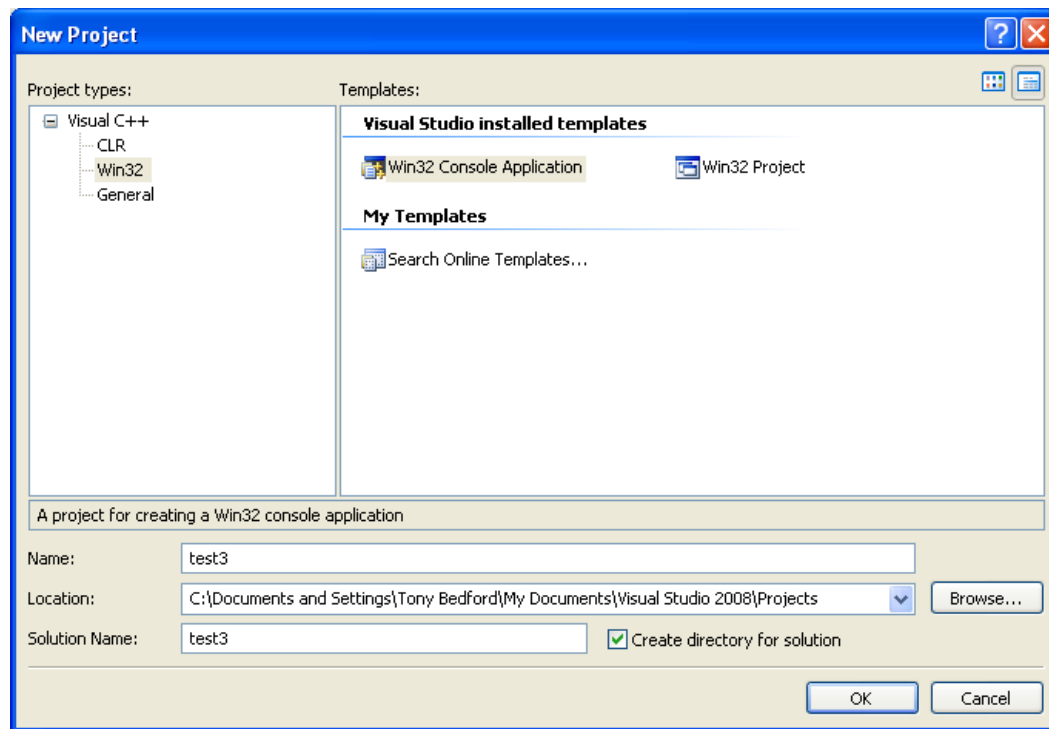

Initially, the procedure for building an application to use either the static or dynamic library is the same. You then carry out some additional steps depending on whether you are building your application to use the [static \[3002\]](#) or [dynamic \[3004\]](#) library.

1. Select **File**, **New**, **Project** from the main menu.

Figure 22.73. Creating a New Project

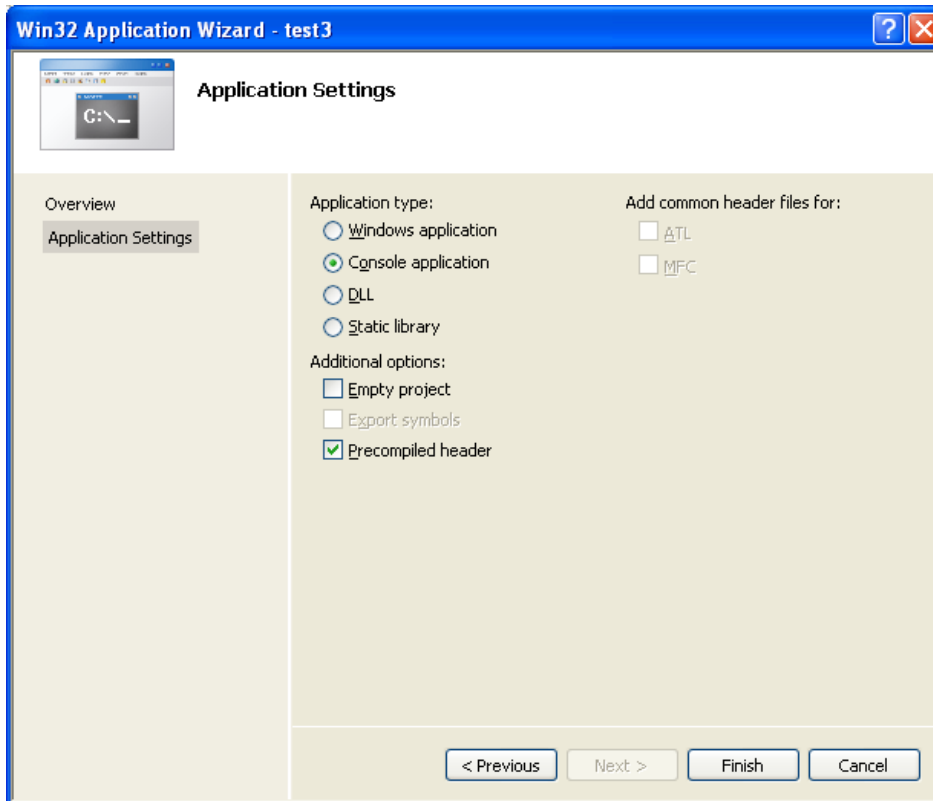

2. In the wizard, select **Visual C++**, **Win32**. From **Visual Studio Installed Templates**, select the application type **Win32 Console Application**. Enter a name for the application, then click **OK**, to move to the Win32 Application Wizard.

Figure 22.74. The New Project Dialog Box

3. In the Win32 Application Wizard, click **Application Settings** and ensure the defaults are selected. The radio button **Console application** and the check box **Precompiled headers** are selected. Click **Finish** to close the wizard.

Figure 22.75. The Win32 Application Wizard

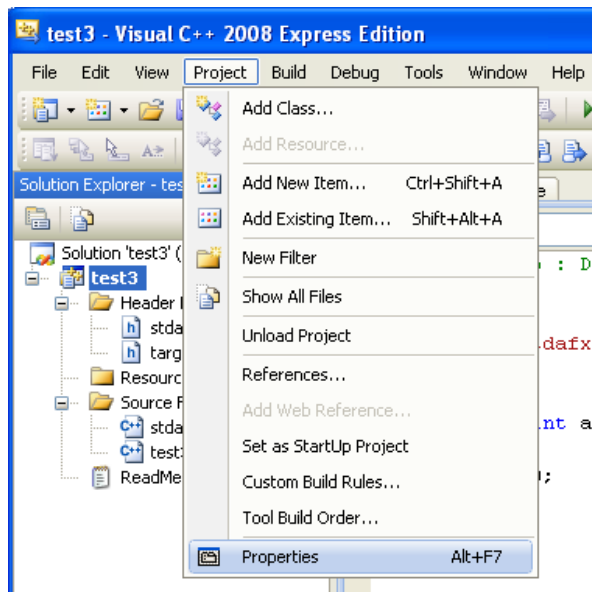

4. From the drop down list box on the toolbar, change from the default **Debug** build to the **Release** build.

Figure 22.76. Selecting the Release Build

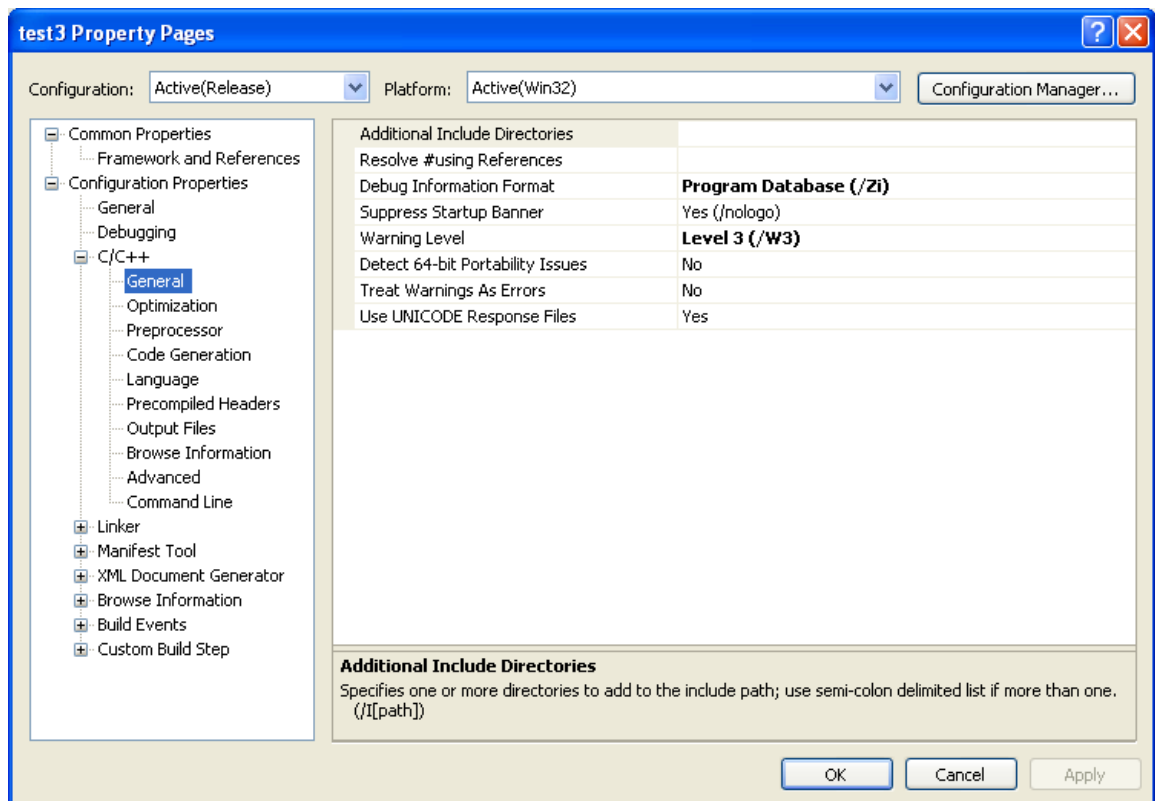

5. From the main menu select Project, Properties. This can also be accessed using the hot key **ALT + F7**.

Figure 22.77. Selecting Project Properties from the Main Menu

6. Under **Configuration Properties**, open the tree view.
7. Select **C++**, **General** in the tree view.

Figure 22.78. Setting Properties

- Now ensure that Visual Studio can find the MySQL include directory. This directory includes header files that can optionally be installed when installing MySQL Server.

Figure 22.79. MySQL Include Directory

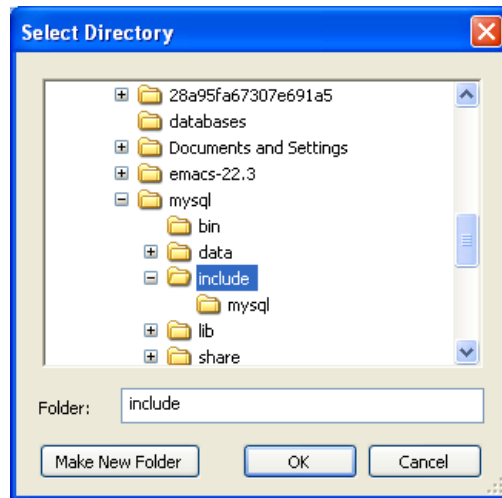

```
Command Prompt
C:\mysql\include>dir
Volume in drive C has no label.
Volume Serial Number is 9484-B7C3

Directory of C:\mysql\include

10/12/2008  13:56    <DIR>          .
10/12/2008  13:56    <DIR>          ..

15/11/2008  06:53        69,632   zlib.pdb
                12 File(s)      20,781,234 bytes
                2 Dir(s)  4,091,240,448 bytes free

C:\mysql\lib\opt>
```

11. In the tree view, open **Linker, General, Additional Library Directories**.

Figure 22.82. Additional Library Directories

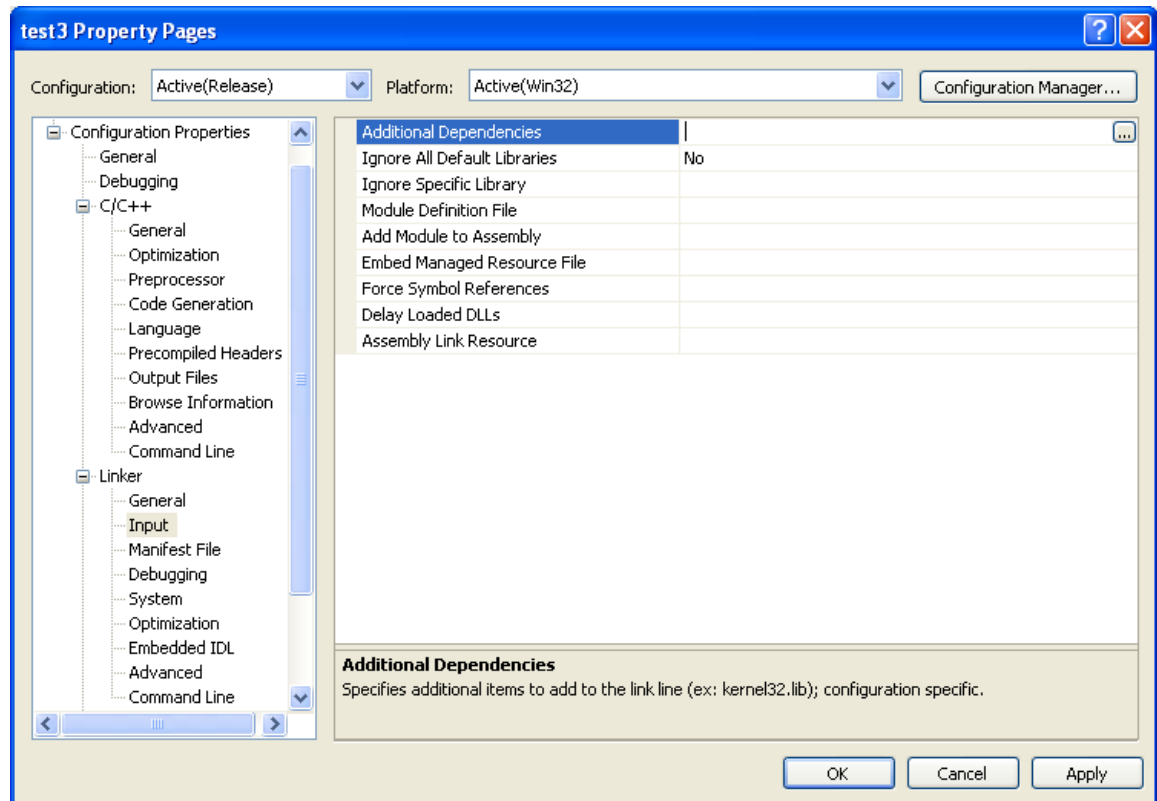

12. Add the `lib/opt` directory into the **Additional Library Directories** text field. This enables the library file `libmysql.lib` to be found.

Figure 22.83. Additional Library Directories Dialog

The remaining steps depend on whether you are building an application to use the MySQL Connector/C++ static or dynamic library. If you are building your application to use the dynamic library [go here \[3004\]](#). If you are building your application to use the static library, carry out the following steps:

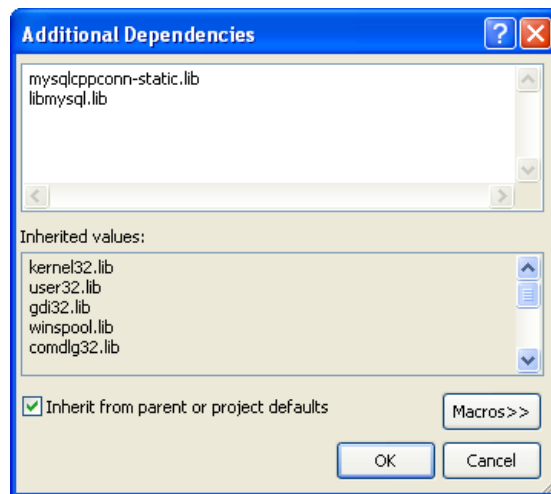

1. Then open **Linker, Input, Additional Dependencies**.

Figure 22.84. Additional Dependencies

2. Enter `mysqlcppconn-static.lib` and `libmysql.lib`.

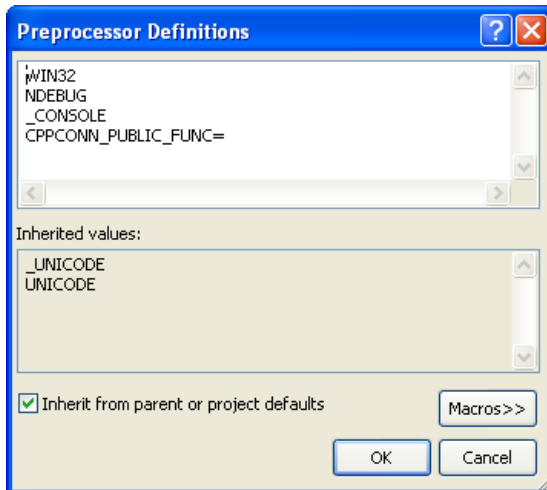

Figure 22.85. Adding Additional Dependencies

3. By default `CPPCONN_PUBLIC_FUNC` is defined to declare functions to be compatible with an application that calls a DLL. If building an application to call the static library, ensure that function prototypes are compatible with this. In this case, define `CPPCONN_PUBLIC_FUNC` to be an empty string, so that functions are declared with the correct prototype.

In the **Project, Properties** tree view, under **C++**, **Preprocessor**, enter `CPPCONN_PUBLIC_FUNC=` into the **Preprocessor Definitions** text field.

Figure 22.86. Setting the CPPCONN_PUBLIC_FUNC Define

Note

Make sure you enter `CPPCONN_PUBLIC_FUNC=` and not `CPPCONN_PUBLIC_FUNC`, so that it is defined as an empty string.

If building an application to use the MySQL Connector/C++ dynamically linked library carry out these steps:

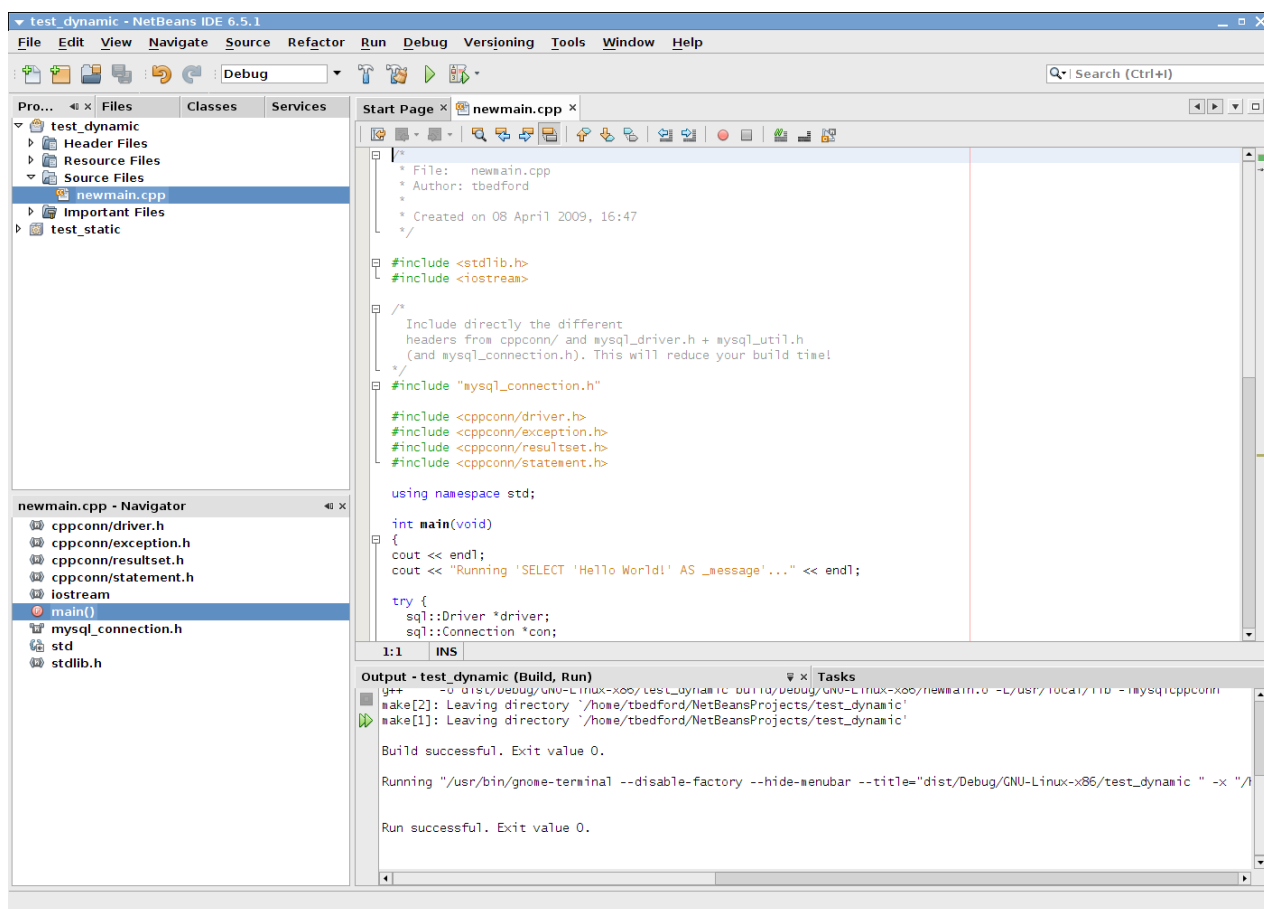

1. Under **Linker, Input**, add `mysqlcppconn.lib` into the **Additional Dependencies** text field.
2. `mysqlcppconn.dll` must be in the same directory as the application executable, or somewhere on the system's path, so that the application can access the MySQL Connector/C++ Dynamic Linked Library at runtime.

Copy `mysqlcppconn.dll` to the same directory as the application. Alternatively, extend the `PATH` environment variable using `SET PATH=%PATH%;C:\path\to\cpp`. Alternatively, you can copy `mysqlcppconn.dll` to the Windows installation Directory, typically `c:\windows`.

22.4.4. MySQL Connector/C++ Building Linux Applications with NetBeans

This section describes how to build MySQL Connector/C++ applications for Linux using the NetBeans IDE.

Figure 22.87. The NetBeans IDE

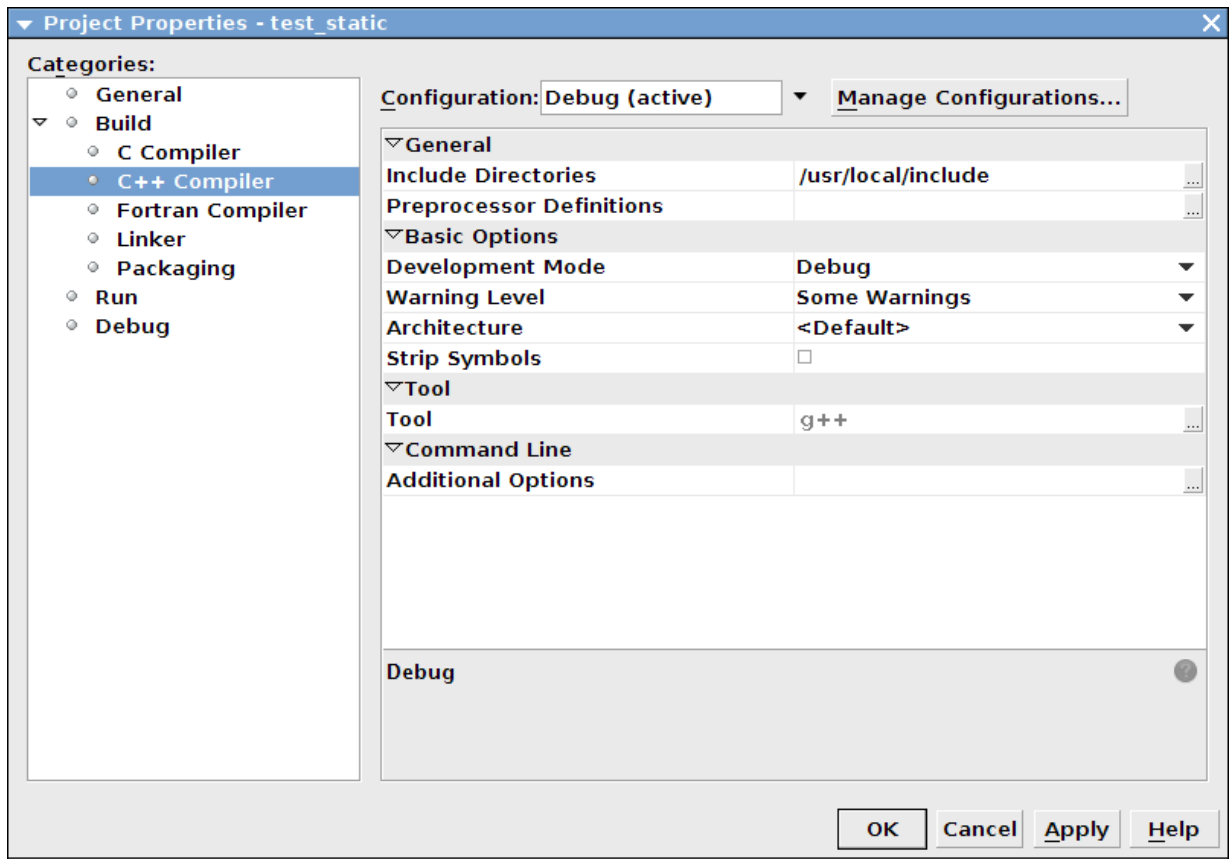

Note

To avoid potential crashes the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

1. The first step of building your application is to create a new project. Select **File**, **New Project**. Choose a **C/C++ Application** and click **Next**.
2. Give the project a name and click **Finish**. A new project is created.
3. In the **Projects** tab, right-click **Source Files** and select **New**, then **Main C++ File...**
4. Change the filename, or simply select the defaults and click **Finish** to add the new file to the project.
5. Now add some working code to your main source file. Explore your MySQL Connector/C++ installation and navigate to the [examples](#) directory.
6. Select a suitable example, such as [standalone_example_docs1.cpp](#). Copy all the code in this file, and use it to replace the code in your existing main source file. Amend the code to reflect the connection properties required for your test database. You now have a working example that will access a MySQL database using MySQL Connector/C++.
7. At this point, NetBeans is showing some errors in the source code. Direct NetBeans to the necessary header files to include. Select **File**, **Project Properties** from the main menu.

8. In the **Categories:** tree view panel, navigate to **Build, C++ Compiler**.
9. In the **General** panel, select **Include Directories**.
10. Click the **...** button.
11. Click **Add**, then navigate to the directory where the MySQL Connector/C++ header files are located. This will be `/usr/local/include` unless you have installed the files to a different location. Click **Select**. Click **OK**.

Figure 22.88. Setting the Header Include Directory

12. Click **OK** again to close the **Project Properties** dialog.

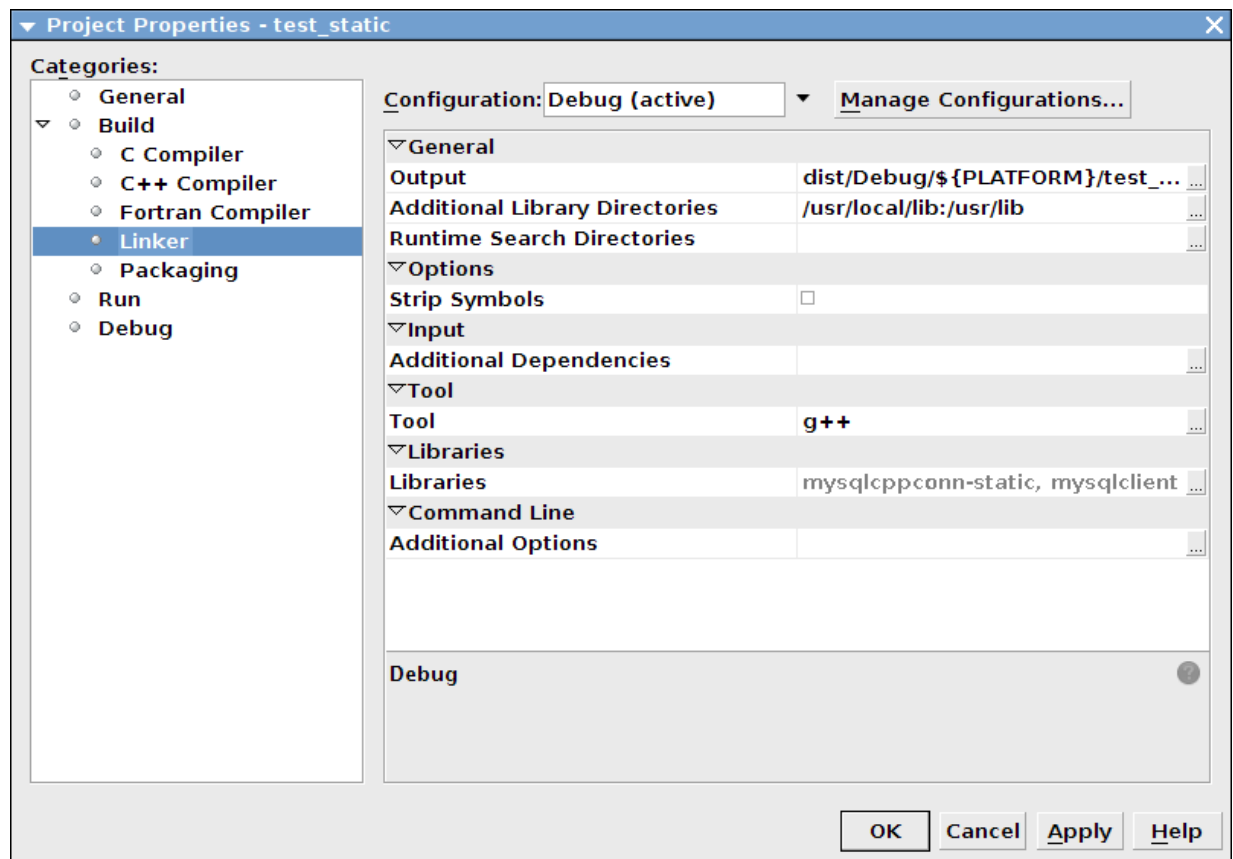

At this point, you have created a NetBeans project, containing a single C++ source file. You have also ensured that the necessary include files are accessible. Before continuing, decide whether your project is to use the MySQL Connector/C++ static or dynamic library. The project settings are slightly different in each case, because you link against a different library.

Using the static library

To use the static library, link against two library files, `libmysqlcppconn-static.a` and `libmysqlclient.a`. The locations of the files depend on your setup, but typically the former are in `/usr/local/lib` and the latter in `/usr/lib`. Note the file `libmysqlclient.a` is not part of MySQL Connector/C++, but is the MySQL Client Library file distributed with MySQL Server. Remember, the MySQL Client Library is an optional component as part of the MySQL Server installation process. Note the MySQL Client Library is also available as part of the MySQL Connector/C distribution.

1. The first step is to set the project to link the necessary library files. Select **File**, **Project Properties** from the main menu.
2. In the **Categories** tree view, navigate to **Linker**.
3. In the **General** panel, select **Additional Library Directories**. Click the **...** button.
4. Select and add the `/usr/lib` and `/usr/local/lib` directories.
5. In the same panel, add the two library files required for static linking as discussed earlier. The properties panel should then look similar to the following screenshot:

Figure 22.89. Setting the Static Library Directories and File Names

6. Click OK to close the **Project Properties** dialog.

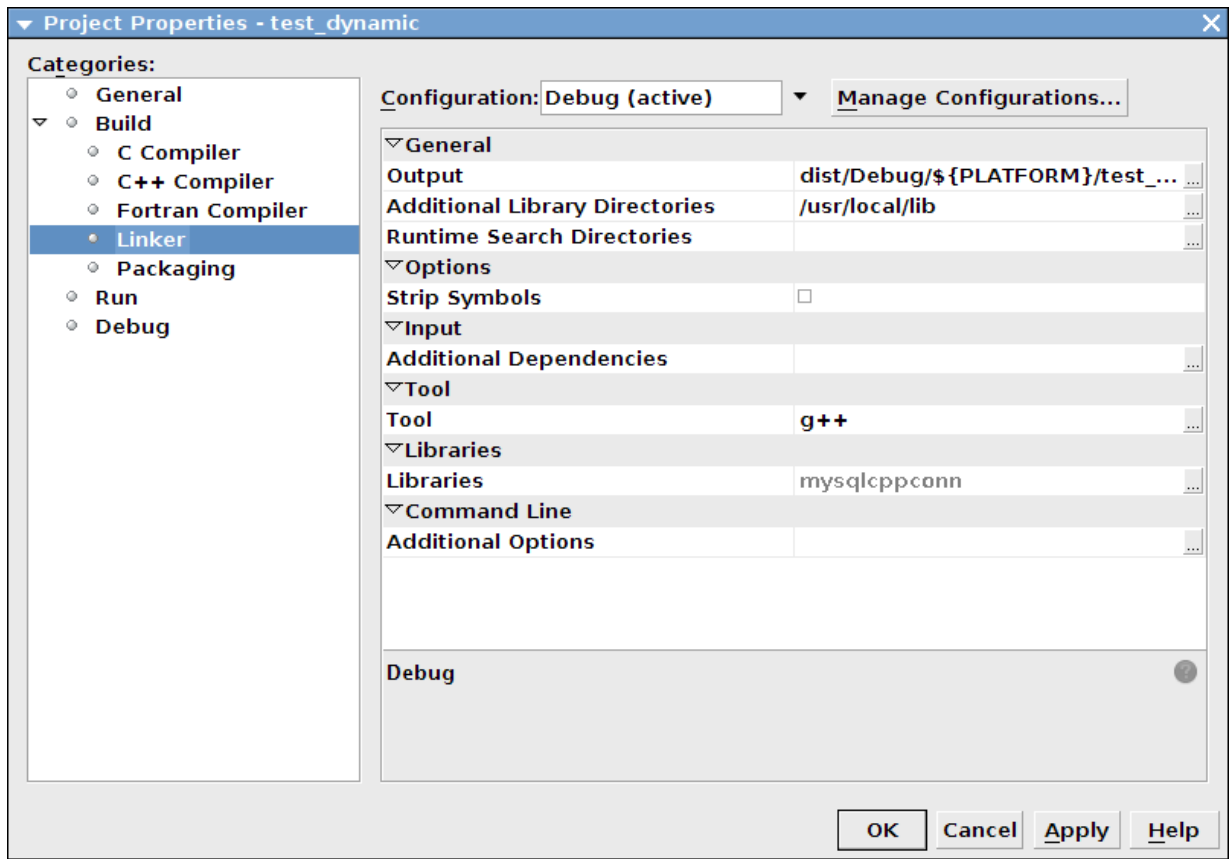

Using the dynamic library

For your application to use the MySQL Connector/C++ dynamic library, you link your project with a single library file, `libmysqlcppconn.so`. The location of this file depends on how you configured your installation of MySQL Connector/C++, but is typically `/usr/local/lib`.

1. The first step is to set the project to link the necessary library file. Select **File**, **Project Properties** from the main menu.
2. In the **Categories** tree view, navigate to **Linker**.
3. In the **General** panel, select **Additional Library Directories**. Click the **...** button.

4. Select and add the `/usr/local/lib` directories.
5. In the same panel, add the library file required for static linking as discussed earlier. The properties panel should then look similar to the following screenshot:

Figure 22.90. Setting the Dynamic Library Directory and File Name

6. Click OK to close the Project Properties dialog.

Having configured your project, you build it by selecting **Run, Build Main Project** from the main menu. You then run the project using **Run, Run Main Project**.

On running the application, you should see a screen similar to the following (this is actually the static version of the application shown):

Figure 22.91. The Example Application RunningA screenshot of a terminal window titled "dist/Debug/GNU-Linux-x86/test_static". The window contains the following text:

```
Running 'SELECT 'Hello World!' AS _message'...  
... MySQL replies: Hello World!  
... MySQL says it again: Hello World!  
  
[Press Enter to close window]
```

**Note**

Note the above settings and procedures were carried out for the default [Debug](#) configuration. To create a [Release](#) configuration, select that configuration before setting the Project Properties.

22.4.5. MySQL Connector/C++ Getting Started: Usage Examples

The download package contains usage examples in the directory [examples/](#). The examples explain the basic usage of the following classes:

- [Connection](#)
- [Driver](#)
- [PreparedStatement](#)
- [ResultSet](#)
- [ResultSetMetaData](#)
- [Statement](#)

The examples cover:

- Using the [Driver](#) class to connect to MySQL
- Creating tables, inserting rows, fetching rows using (simple) statements
- Creating tables, inserting rows, fetching rows using prepared statements
- Hints for working around prepared statement limitations
- Accessing result set metadata

The examples in this document are only code snippets. The code snippets provide a brief overview on the API. They are not complete programs. Please check the [examples/](#) directory of your MySQL Connector/C++ installation for complete programs. Please also read the [README](#) file in the [examples/](#) directory. To test the example code, first edit the [examples.h](#) file in the [examples/](#) directory, to add your connection information. Then rebuild the code by issuing a `make` command.

The examples in the [examples/](#) directory include:

- [examples/connect.cpp](#):
How to create a connection, insert data into MySQL and handle exceptions.
- [examples/connection_meta_schemaobj.cpp](#):
How to obtain metadata associated with a connection object, for example, a list of tables, databases, MySQL version, connector version.
- [examples/debug_output.cpp](#):
How to activate and deactivate the MySQL Connector/C++ debug protocol.
- [examples/exceptions.cpp](#):
A closer look at the exceptions thrown by the connector and how to fetch error information.
- [examples/prepared_statements.cpp](#):
How to run Prepared Statements including an example how to handle SQL commands that cannot be prepared by the MySQL Server.
- [examples/resultset.cpp](#):
How to fetch data and iterate over the result set (cursor).
- [examples/resultset_meta.cpp](#):
How to obtain metadata associated with a result set, for example, number of columns and column types.
- [examples/resultset_types.cpp](#):
Result sets returned from metadata methods - this is more a test than much of an example.
- [examples/standalone_example.cpp](#):
Simple standalone program not integrated into regular `CMake` builds.
- [examples/statements.cpp](#):
How to run SQL commands without using Prepared Statements.
- [examples/cpp_trace_analyzer.cpp](#):
This example shows how to filter the output of the [debug trace](#). Please see the inline comments for further documentation. This script is unsupported.

22.4.5.1. MySQL Connector/C++ Connecting to MySQL

A connection to MySQL is established by retrieving an instance of `sql::Connection` from a `sql::mysql::MySQL_Driver` object. A `sql::mysql::MySQL_Driver` object is returned by `sql::mysql::MySQL_Driver::get_mysql_driver_instance()`.

```

sql::mysql::MySQL_Driver *driver;
sql::Connection *con;

driver = sql::mysql::MySQL_Driver::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");

delete con;

```

Make sure that you free the `sql::Connection` object as soon as you do not need it any more. But do not explicitly free the connector object!

22.4.5.2. MySQL Connector/C++ Running a simple query

For running simple queries, you can use the methods `sql::Statement::execute()`, `sql::Statement::executeQuery()` and `sql::Statement::executeUpdate()`. Use the method `sql::Statement::execute()` if your query does not return a result set or if your query returns more than one result set. See the `examples/` directory for more on this.

```

sql::mysql::MySQL_Driver *driver;
sql::Connection *con;
sql::Statement *stmt;

driver = sql::mysql::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");

stmt = con->createStatement();
stmt->execute("USE " EXAMPLE_DB);
stmt->execute("DROP TABLE IF EXISTS test");
stmt->execute("CREATE TABLE test(id INT, label CHAR(1))");
stmt->execute("INSERT INTO test(id, label) VALUES (1, 'a')");

delete stmt;
delete con;

```

Note that you have to free `sql::Statement` and `sql::Connection` objects explicitly using `delete`.

22.4.5.3. MySQL Connector/C++ Fetching results

The API for fetching result sets is identical for (simple) statements and prepared statements. If your query returns one result set, use `sql::Statement::executeQuery()` or `sql::PreparedStatement::executeQuery()` to run your query. Both methods return `sql::ResultSet` objects. The previous version does buffer all result sets on the client to support cursors.

```

// ...
sql::Connection *con;
sql::Statement *stmt;
sql::ResultSet *res;
// ...
stmt = con->createStatement();
// ...

res = stmt->executeQuery("SELECT id, label FROM test ORDER BY id ASC");
while (res->next()) {
    // You can use either numeric offsets...
    cout << "id = " << res->getInt(1); // getInt(1) returns the first column
    // ... or column names for accessing results.
    // The latter is recommended.
    cout << ", label = " << res->getString("label") << " " << endl;
}

delete res;
delete stmt;
delete con;

```

**Note**

Note in the preceding code snippet that column indexing starts from 1.

Note that you have to free `sql::Statement`, `sql::Connection` and `sql::ResultSet` objects explicitly using delete.

The usage of cursors is demonstrated in the examples contained in the download package.

22.4.5.4. MySQL Connector/C++ Using Prepared Statements

If you are not familiar with Prepared Statements on MySQL have an extra look at the source code comments and explanations in the file `examples/prepared_statement.cpp`.

`sql::PreparedStatement` is created by passing an SQL query to `sql::Connection::prepareStatement()`. As `sql::PreparedStatement` is derived from `sql::Statement`, you will feel familiar with the API once you have learned how to use (simple) statements (`sql::Statement`). For example, the syntax for fetching results is identical.

```
// ...
sql::Connection *con;
sql::PreparedStatement *prep_stmt
// ...

prep_stmt = con->prepareStatement("INSERT INTO test(id, label) VALUES (?, ?)");

prep_stmt->setInt(1, 1);
prep_stmt->setString(2, "a");
prep_stmt->execute();

prep_stmt->setInt(1, 2);
prep_stmt->setString(2, "b");
prep_stmt->execute();

delete prep_stmt;
delete con;
```

As usual, you have to free `sql::PreparedStatement` and `sql::Connection` objects explicitly.

22.4.5.5. MySQL Connector/C++ Complete Example 1

The following code shows a complete example of how to use MySQL Connector/C++:

```
/* Copyright 2008, 2010, Oracle and/or its affiliates. All rights reserved.

*/
```

```
/* Standard C++ includes */
#include <stdlib.h>
#include <iostream>

/*
   Include directly the different
   headers from cppconn/ and mysql_driver.h + mysql_util.h
   (and mysql_connection.h). This will reduce your build time!
*/
#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>

using namespace std;

int main(void)
{
    cout << endl;
    cout << "Running 'SELECT 'Hello World!' AS _message' >
        AS _message'..." << endl;

    try {
        sql::Driver *driver;
        sql::Connection *con;
        sql::Statement *stmt;
        sql::ResultSet *res;

        /* Create a connection */
        driver = get_driver_instance();
        con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
        /* Connect to the MySQL test database */
        con->setSchema("test");

        stmt = con->createStatement();
        res = stmt->executeQuery("SELECT 'Hello World!' AS _message");
        while (res->next()) {
            cout << "\t... MySQL replies: ";
            /* Access column data by alias or column name */
            cout << res->getString("_message") << endl;
            cout << "\t... MySQL says it again: ";
            /* Access column data by numeric offset, 1 is the first column */
            cout << res->getString(1) << endl;
        }
        delete res;
        delete stmt;
        delete con;

    } catch (sql::SQLException &e) {
        cout << "# ERR: SQLException in " << __FILE__;
        cout << "(" << __FUNCTION__ << ") on line " >
            << __LINE__ << endl;
        cout << "# ERR: " << e.what();
        cout << " (MySQL error code: " << e.getErrorCode();
        cout << ", SQLState: " << e.getSQLState() << ")" << endl;
    }

    cout << endl;

    return EXIT_SUCCESS;
}
```

22.4.5.6. MySQL Connector/C++ Complete Example 2

The following code shows a complete example of how to use MySQL Connector/C++:

```
/* Copyright 2008, 2010, Oracle and/or its affiliates. All rights reserved.

This program is free software; you can redistribute it and/or modify
it under the terms of the GNU General Public License as published by
the Free Software Foundation; version 2 of the License.

   (and mysql_connection.h). This will reduce your build time!
*/
#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

using namespace std;

int main(void)
{
    cout << endl;
    cout << "Let's have MySQL count from 10 to 1..." << endl;

    try {
        sql::Driver *driver;
        sql::Connection *con;
        sql::Statement *stmt;
        sql::ResultSet *res;
        sql::PreparedStatement *pstmt;

        /* Create a connection */
        driver = get_driver_instance();
        con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
        /* Connect to the MySQL test database */
        con->setSchema("test");

        stmt = con->createStatement();
        stmt->execute("DROP TABLE IF EXISTS test");
        stmt->execute("CREATE TABLE test(id INT)");
        delete stmt;
    }
}
```

```

/* '?' is the supported placeholder syntax */
pstmt = con->prepareStatement("INSERT INTO test(id) VALUES (?)");
for (int i = 1; i <= 10; i++) {
    pstmt->setInt(1, i);
    pstmt->executeUpdate();
}
delete pstmt;

/* Select in ascending order */
pstmt = con->prepareStatement("SELECT id FROM test ORDER BY id ASC");
res = pstmt->executeQuery();

/* Fetch in reverse = descending order! */
res->afterLast();
while (res->previous())
    cout << "\t... MySQL counts: " << res->getInt("id") << endl;
delete res;

delete pstmt;
delete con;

} catch (sql::SQLException &e) {
    cout << "# ERR: SQLException in " << __FILE__;
    cout << "(" << __FUNCTION__ << " on line " <<
        << __LINE__ << endl;
    cout << "# ERR: " << e.what();
    cout << " (MySQL error code: " << e.getErrorCode();
    cout << ", SQLState: " << e.getSQLState() << >
        " )" << endl;
}

cout << endl;

return EXIT_SUCCESS;
}

```

22.4.6. MySQL Connector/C++ Tutorials

Here are some tutorials on using MySQL Connector/C++. Also consult the examples in [Section 22.4.5, “MySQL Connector/C++ Getting Started: Usage Examples”](#).

Setting up the World database for use in the tutorials

These tutorials refer to tables and sample data from the [World](#) database, which you can download from the [MySQL Documentation](#) page. Look for the section called “Example Databases”.

Tutorial framework code

These examples all use the following framework, to avoid repeating code:

```

#include <stdlib.h>
#include <iostream>
#include <sstream>
#include <stdexcept>

#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

#define EXAMPLE_HOST "localhost"

```

```

#define EXAMPLE_USER "root"
#define EXAMPLE_PASS ""
#define EXAMPLE_DB "world"

using namespace std;

int main(int argc, const char **argv)
{
    string url(argc >= 2 ? argv[1] : EXAMPLE_HOST);
    const string user(argc >= 3 ? argv[2] : EXAMPLE_USER);
    const string pass(argc >= 4 ? argv[3] : EXAMPLE_PASS);
    const string database(argc >= 5 ? argv[4] : EXAMPLE_DB);

    cout << "Connector/C++ tutorial framework..." << endl;
    cout << endl;

    try {

/* INSERT TUTORIAL CODE HERE! */

    } catch (sql::SQLException &e) {
        /*
         * The MySQL Connector/C++ throws three different exceptions:
         *
         * - sql::MethodNotImplementedException (derived from sql::SQLException)
         * - sql::InvalidArgumentException (derived from sql::SQLException)
         * - sql::SQLException (derived from std::runtime_error)
         */
        cout << "# ERR: SQLException in " << __FILE__ ;
        cout << "(" << __FUNCTION__ << ") on line " << __LINE__ << endl;
        /* Use what() (derived from std::runtime_error) to fetch the error message */
        cout << "# ERR: " << e.what();
        cout << " (MySQL error code: " << e.getErrorCode();
        cout << ", SQLState: " << e.getSQLState() << " )" << endl;

        return EXIT_FAILURE;
    }

    cout << "Done," << endl;
    return EXIT_SUCCESS;
}

```

To compile and run the framework

First, copy and paste the framework code to a file such as `frmwk.cpp`. Edit the `#define` statements to reflect your connection details (server, user, password, database).

To compile the framework, for example on Mac OS X, type:

```
shell> g++ -o frmwk -I/usr/local/include -I/usr/local/include/cppconn -lmysqlcppconn frmwk.cpp
```

To run the framework, enter the following:

```
shell> ./frmwk
```

You will see a simple message. You are now ready to continue to the tutorials.

22.4.6.1. Tutorial: Calling Stored Procedures with Statements in MySQL Connector/C++

Stored procedures can be called using both Statements and Prepared Statements. This tutorial looks at calling stored procedures using Statements. The following tutorial [Section 22.4.6.2, "Tutorial: Calling Stored Procedures with Prepared Statements in MySQL Connector/C++"](#) will cover the use of Prepared Statements.

You can construct and call various combinations of stored procedures:

1. A stored procedure that does not return any result. For example, such a stored procedure can log non-critical information, or change database data in a straightforward way.
2. A stored procedure that returns an output parameter. For example, such a procedure can indicate success or failure, query a single item of data, or combine multiple data items into a single result.
3. A stored procedure that returns a result set. The procedure can execute a query that matches an arbitrary number of table rows. Your application loops through the result set to display, transform, or otherwise process each item.

The following stored procedures illustrate each of these scenarios.

The following routine adds a country into the World database, but does not return a result. This corresponds to Scenario 1 above.

```
CREATE PROCEDURE add_country (IN country_code CHAR(3), IN country_name CHAR(52), IN continent_name CHAR(30))
BEGIN
    INSERT INTO Country(Code, Name, Continent) VALUES (country_code, country_name, continent_name);
END
```

The next routine returns the population of a specified country, and corresponds to Scenario 2 above:

```
CREATE PROCEDURE get_pop (IN country_name CHAR(52), OUT country_pop INT(11))
BEGIN
    SELECT Population INTO country_pop FROM Country WHERE Name = country_name;
END
```

The next routine is an example of a procedure returning a result set containing multiple records. This routine corresponds to Scenario 3 above.

```
CREATE PROCEDURE get_data ()
BEGIN
    SELECT Code, Name, Population, Continent FROM Country WHERE Continent = "Oceania" AND Population < 1000000;
    SELECT Code, Name, Population, Continent FROM Country WHERE Continent = "Europe" AND Population < 1000000;
    SELECT Code, Name, Population, Continent FROM Country WHERE Continent = "North America" AND Population < 1000000;
END
```

Enter and test the stored procedures to ensure no errors have been introduced. You are now ready to start writing applications using Connector/C++ that call stored procedures.

Scenario 1 - Stored procedure does not return a result set

The first case illustrates Scenario 1, calling a Stored procedure that does not return a result set.

1. Make a copy of the tutorial framework code.
2. Insert the following code into the framework at the correct location (denoted by an INSERT HERE comment in the framework).

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

// We don't need to check the return value explicitly, if it indicates
// an error Connector/C++ will generate an exception.
stmt->execute("CALL add_country(\"ATL\", \"Atlantis\", \"North America\")");
```

3. Compile the program using the following command:

```
shell> g++ -o sp_scenario1 -I/usr/local/include/cppconn/ -lmysqlcppconn sp_scenario1.cpp
```

4. Run the program by typing:

```
shell> ./sp_scenario1
```

5. Using the `mysql` Command Line Client, or other suitable tool, check the World database to determine that it has been updated correctly. You can use a query such as:

```
SELECT Code, Name, Continent FROM Country WHERE Code="ATL";
```

The code in this case simply creates a statement and then invokes the execute method on it, passing the call to the stored procedure as a parameter. The stored procedure itself does not return a value, although it is important to note there will always be a return value from the call - this is simply the call status. MySQL Connector/C++ handles this status for you, so you do not need code to handle it explicitly. If the call fails for some reason, an exception will be raised, and this will be handled by the `catch` statement in the code.

Scenario 2 - Stored procedure returns an output parameter

You will now see how to handle a stored procedure that returns an output parameter.

1. Enter the following code into the tutorial framework code:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_pop(\"Uganda\", @pop)");

std::auto_ptr<sql::ResultSet> res(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of Uganda: " << res->getString("_reply") << endl;

stmt->execute("CALL get_pop_continent(\"Asia\", @pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of Asia: " << res->getString("_reply") << endl;

stmt->execute("CALL get_world_pop(@pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of World: " << res->getString("_reply") << endl;
```

2. Compile the program using the following command:

```
shell> g++ -o sp_scenario2 -I/usr/local/include/cppconn/ -lmysqlcppconn sp_scenario2.cpp
```

3. Run the program by typing:

```
shell> ./sp_scenario2
```

Note the output generated by the program.

In this scenario, the stored procedure sets an output parameter. This is not returned as such, but needs to be obtained using a query. If running the SQL statements directly, this might be similar to the following:

```
CALL get_world_pop(@pop);
SELECT @pop;
```

In the C++ code, a similar sequence is carried out. First, the `CALL` is executed as seen earlier. To obtain the output parameter, an additional query must be executed. This query results in a `ResultSet` that can then be processed in a `while` loop. The simplest way to retrieve the data in this case is to use a `getString` method on the `ResultSet`, passing the name of the variable to access. In this example `_reply` is used as a placeholder for the variable and therefore is used as the key to access the correct element of the result dictionary.

Scenario 3 - Stored procedure returns a Result Set

You will now see how to handle a stored procedure that returns a result set.

1. Enter the following code into the tutorial framework code:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_stats()");
std::auto_ptr< sql::ResultSet > res;
do {
    res.reset(stmt->getResultSet());
    while (res->next()) {
        cout << "Result: " << res->getString(1) << endl;
    }
} while (stmt->getMoreResults());
```

2. Compile the program using the following command:

```
shell> g++ -o sp_scenario3 -I/usr/local/include/cppconn/ -lmysqlcppconn sp_scenario3.cpp
```

3. Run the program by typing:

```
shell> ./sp_scenario3
```

Note the output generated by the program.

The code is similar to the examples you have previously seen. The code of particular interest in this case is:

```
do {
    res.reset(stmt->getResultSet());
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
            << " Population: " << res->getInt("Population")
            << endl;
    }
} while (stmt->getMoreResults());
```

The `CALL` is executed as before, with the results being returned into multiple `ResultSets`. This is because the Stored Procedure in this case uses multiple `SELECT` statements. In this example, the output shows that three Result Sets are processed, because there are three `SELECT` statements in the Stored Procedure. All of the Result Sets have more than one row.

The results are processed using the pattern:

```
do {
    Get Result Set
    while (Get Result) {
        Process Result
```

```

}
} while (Get More Result Sets);

```

Note

This pattern would be used even if the Stored Procedure carried out a single `SELECT` and you knew there was only one result set. This is a requirement of the underlying protocol.

22.4.6.2. Tutorial: Calling Stored Procedures with Prepared Statements in MySQL Connector/C++

Before working through this tutorial, it is recommended you first work through the previous tutorial [Section 22.4.6.1, "Tutorial: Calling Stored Procedures with Statements in MySQL Connector/C++"](#).

Scenario 1 - Using a Prepared Statement to prepare a Stored Procedure that does not return a result set

1. Add the following code to the `try` block of the tutorial framework:

```

vector<string> code_vector;
code_vector.push_back("SLD");
code_vector.push_back("DSN");
code_vector.push_back("ATL");

vector<string> name_vector;
name_vector.push_back("Sealand");
name_vector.push_back("Disneyland");
name_vector.push_back("Atlantis");

vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");
cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement > pstmt;

pstmt.reset(con->prepareStatement("CALL add_country(?,?,?)"));
for (int i=0; i<3; i++)
{
    pstmt->setString(1,code_vector[i]);
    pstmt->setString(2,name_vector[i]);
    pstmt->setString(3,cont_vector[i]);

    pstmt->execute();
}

```

Also, add `#include <vector>` to the top of your code, because vectors are used to store sample data.

2. Compile the code using the following command:

```
g++ -o ps_scenario1 -I/usr/local/include/cppconn/ -lmysqlcppconn ps_scenario1.cpp
```

3. Run the code using the command:

```
./ps_scenario1
```

4. You can test the database has been updated correctly by using a query such as:

```
SELECT Code, Name, Continent FROM Country WHERE Code = "DSN" OR Code="ATL" OR Code="SLD";
```

The code is relatively simple, as no processing is required to handle Result Sets. The procedure call, `CALL add_country(?, ?, ?)`, is made using placeholders for input parameters denoted by '?'. These placeholders are replaced by values using the Prepared Statement's `setString` method in this case. The `for` loop is set up to iterate 3 times, as there are three data sets in this example. The same Prepared Statement is executed three times, each time with different input parameters.

Scenario 2 - Using a Prepared Statement to prepare a Stored Procedure that uses an output parameter

In this scenario a different Stored Procedure is going to be used compared to the one used in the tutorial [Section 22.4.6.1, "Tutorial: Calling Stored Procedures with Statements in MySQL Connector/C++"](#). This is to illustrate passing an input parameter as well as fetching an output parameter. The stored routine is as follows:

```
CREATE PROCEDURE get_pop_continent (IN continent_name CHAR(30), OUT continent_pop INT(11))
BEGIN
    SELECT SUM(Population) INTO continent_pop FROM Country WHERE Continent = continent_name;
END
```

1. Copy the following code into the try block of the tutorial framework code:

```
vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");
cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::Statement > stmt(con->createStatement());
std::auto_ptr< sql::PreparedStatement > pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_pop_continent(?, @pop)"));

for (int i=0; i<3; i++)
{
    pstmt->setString(1, cont_vector[i]);
    pstmt->execute();
    res.reset(stmt->executeQuery("SELECT @pop AS _population"));
    while (res->next())
        cout << "Population of " << cont_vector[i] << " is " << res->getString("_population") << endl;
}
```

You will also need to add the line `#include <vector>` to the top of the code, as vectors are used in this example.

2. Compile the code using:

```
shell> g++ -o ps_scenario2 -I/usr/local/include/cppconn/ -lmysqlcppconn ps_scenario2.cpp
```

3. Run the code using:

```
shell> ./ps_scenario2
```

4. Make a note of the output.

In this scenario a Prepared Statement is created that calls the Stored Procedure `get_pop_continent`. This procedure takes an input parameter, and also returns an output parameter. The approach used is to create another statement that can be used to fetch the output parameter using a `SELECT` query. Note that when the Prepared Statement is created, the input parameter to the Stored Procedure is denoted by '?'. Prior to execution of Prepared Statement it is necessary to replace this placeholder by an actual value. This is done using methods such as `setString` and `setInt`, for example:

```
pstmt->setString(1,cont_vector[i]);
```

Although for the query used to obtain the output parameter a single result set is expected, it is important to use the `while` loop to catch more than one result, to avoid the possibility of the connection becoming unstable.

Scenario 3 - Using a Prepared Statement to prepare a Stored Procedure that returns multiple Result Sets

Note

Note this scenario is not supported on versions of MySQL prior to 5.5.3. This is due to a limitation in the client/server protocol.

1. Enter the following code into the `try` block of the tutorial framework:

```
sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement > pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_data("));
res.reset(pstmt->executeQuery());

do {
    res.reset(pstmt->getResultSet());
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
            << " Population: " << res->getInt("Population")
            << endl;
    }
} while (pstmt->getMoreResults());
```

2. Compile the code using the following command:

```
shell> g++ -o ps_scenario3 -I/usr/local/include/cppconn/ -lmysqlcppconn ps_scenario3.cpp
```

3. Run the program using the command:

```
shell> ./ps_scenario3
```

4. Make a note of the output generated.

The code executes the Stored Procedure using a Prepared Statement. The standard do-while construct is used to ensure that all Result Sets are fetched. In this case the returned values are fetched from the Result Sets using the `getInt` and `getString` methods.

22.4.7. MySQL Connector/C++ Debug Tracing

Although a debugger can be used to debug your application, you may find it beneficial to turn on the debug traces of the connector. Some problems happen randomly which makes them difficult to debug using a

debugger. In such cases debug traces and protocol files are more useful because they allow you to trace the activities of all instances of your program.

DTrace is a very powerful technology to trace any application without having to develop an extra trace module for your application. Unfortunately, DTrace is currently only available on Solaris, MacOS 10.5, and FreeBSD.

The MySQL Connector/C++ can write two trace files:

1. Trace file generated by the MySQL Client Library
2. Trace file generated internally by MySQL Connector/C++

The first trace file can be generated by the underlying MySQL Client Library (libmysql). To enable this trace, the connector will call the C-API function `mysql_debug()` internally. As only debug versions of the MySQL Client Library are capable of writing a trace file, compile MySQL Connector/C++ against a debug version of the library if you want to utilize this trace. The trace shows the internal function calls and the addresses of internal objects as shown below:

```
>mysql_stmt_init
| >_mymalloc
| | enter: Size: 816
| | exit: ptr: 0x68e7b8
| <_mymalloc | >init_alloc_root
| | enter: root: 0x68e7b8
| | >_mymalloc
| | | enter: Size: 2064
| | | exit: ptr: 0x68eb28
| ...]
```

The second trace is the MySQL Connector/C++ internal trace. It is available with debug and nondebug builds of the connector as long as you have enabled the tracing module at compile time using `cmake -DMYSQLCPPCONN_TRACE_ENABLE=BOOL=1`. By default, the tracing functionality is not available and calls to trace functions are removed by the preprocessor.

Compiling the connector with tracing functionality enabled will cause two additional tracing function calls per each connector function call. Run your own benchmark to find out how much this will impact the performance of your application.

A simple test using a loop running 30,000 INSERT SQL statements showed no significant real-time impact. The two variants of this application using a trace enabled and trace disabled version of the connector performed equally well. The run time measured in real-time was not significantly impacted as long as writing a debug trace was not enabled. However, there will be a difference in the time spent in the application. When writing a debug trace the IO subsystem may become a bottleneck.

In summary, use connector builds with tracing enabled carefully. Trace enabled versions may cause higher CPU usage even if the overall run time of your application is not impacted significantly.

```
| INF: Tracing enabled
| <MySQL_Connection::setClientOption
| >MySQL_Prepared_Statement::setInt
| INF: this=0x69a2e0
| >MySQL_Prepared_Statement::checkClosed
| <MySQL_Prepared_Statement::checkClosed
| <MySQL_Prepared_Statement::setInt
| ...]
```

The example from `examples/debug_output.cpp` demonstrates how to activate the debug traces in your program. Currently they can only be activated through API calls. The traces are controlled on a per-connection basis. You can use the `setClientOptions()` method of a connection object to activate and

deactivate the generation of a trace. The MySQL Client Library trace is always written into a file, whereas the connector's protocol messages are printed to standard out.

```
sql::Driver *driver;
int on_off = 1;

/* Using the Driver to create a connection */
driver = get_driver_instance();
std::auto_ptr< sql::Connection > con(driver->connect(host, user, pass));

/*
Activate debug trace of the MySQL Client Library (C-API)
Only available with a debug build of the MySQL Client Library!
*/
con->setClientOption("libmysql_debug", "d:t:0,client.trace");

/*
Tracing is available if you have compiled the driver using
cmake -DMYSQLCPPCONN_TRACE_ENABLE=BOOL=1
*/
con->setClientOption("client_trace", &on_off);
```

22.4.8. MySQL Connector/C++ Usage Notes

See the [JDBC overview](#) for information on JDBC 4.0. Please also check the [examples/](#) directory of the download package.

- `DatabaseMetaData::supportsBatchUpdates()` returns `true` because MySQL supports batch updates in general. However, no API calls for batch updates are provided by the MySQL Connector/C++ API.
- Two non-JDBC methods let you fetch and set unsigned integers: `getUInt64()` and `getUInt()`. These are available for `ResultSet` and `PreparedStatement`:
 - `ResultSet::getUInt64()`
 - `ResultSet::getUInt()`
 - `PreparedStatement::setUInt64()`
 - `PreparedStatement::setUInt()`

The corresponding `getLong()` and `setLong()` methods have been removed.

- The method `DatabaseMetaData::getColumnNames()` has 23 columns in its result set, rather than the 22 columns defined by JDBC. The first 22 columns are as described in the JDBC documentation, but column 23 is new:

23. `IS_AUTOINCREMENT`: String which is "YES" if the column is an auto-increment column. Otherwise the string contains "NO".

- MySQL Connector/C++ may return different metadata for the same column.

When you have any column that accepts a charset and a collation in its specification and you specify a binary collation, such as:

```
CHAR(250) CHARACTER SET 'latin1' COLLATE 'latin1_bin'
```

The server sets the `BINARY` flag in the result set metadata of this column. The method `ResultSetMetadata::getColumnTypeName()` uses the metadata and will report, due to the `BINARY` flag, that the column type name is `BINARY`. This is illustrated below:

```
mysql> create table varbin(a varchar(20) character set utf8 collate utf8_bin);
Query OK, 0 rows affected (0.00 sec)

mysql> select * from varbin;
Field 1: `a`
Catalog: `def`
Database: `test`
Table: `varbin`
Org_table: `varbin`
Type: VAR_STRING
Collation: latin1_swedish_ci (8)
Length: 20
Max_length: 0
Decimals: 0
Flags: BINARY

0 rows in set (0.00 sec)

mysql> select * from information_schema.columns where table_name='varbin'\G
***** 1. row *****
      TABLE_CATALOG: NULL
      TABLE_SCHEMA: test
      TABLE_NAME: varbin
      COLUMN_NAME: a
      ORDINAL_POSITION: 1
      COLUMN_DEFAULT: NULL
      IS_NULLABLE: YES
      DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 20
CHARACTER_OCTET_LENGTH: 60
      NUMERIC_PRECISION: NULL
      NUMERIC_SCALE: NULL
CHARACTER_SET_NAME: utf8
      COLLATION_NAME: utf8_bin
      COLUMN_TYPE: varchar(20)
      COLUMN_KEY:
      EXTRA:
      PRIVILEGES: select,insert,update,references
      COLUMN_COMMENT:
1 row in set (0.01 sec)
```

However, `INFORMATION_SCHEMA` gives no hint in its `COLUMNS` table that metadata will contain the `BINARY` flag. `DatabaseMetaData::getColumn()` uses `INFORMATION_SCHEMA`. It will report the type name `CHAR` for the same column. Note, a different type code is also returned.

- The MySQL Connector/C++ class `sql::DataType` defines the following JDBC standard data types: `UNKNOWN`, `BIT`, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INTEGER`, `BIGINT`, `REAL`, `DOUBLE`, `DECIMAL`, `NUMERIC`, `CHAR`, `BINARY`, `VARCHAR`, `VARBINARY`, `LONGVARCHAR`, `LONGVARBINARY`, `TIMESTAMP`, `DATE`, `TIME`, `GEOMETRY`, `ENUM`, `SET`, `SQLNULL`.

However, the following JDBC standard data types are *not* supported by MySQL Connector/C++: `ARRAY`, `BLOB`, `CLOB`, `DISTINCT`, `FLOAT`, `OTHER`, `REF`, `STRUCT`.

- When inserting or updating `BLOB` or `TEXT` columns, MySQL Connector/C++ developers are advised not to use `setString()`. Instead, use the dedicated API function `setBlob()`.

The use of `setString()` can cause a `Packet too large` error message. The error will occur if the length of the string passed to the connector using `setString()` exceeds `max_allowed_packet` (minus a few bytes reserved in the protocol for control purposes). This situation is not handled in MySQL Connector/C++, as this could lead to security issues, such as extremely large memory allocation requests due to malevolently long strings.

However, if `setBlob()` is used, this problem does not arise. This is because `setBlob()` takes a streaming approach based on `std::istream`. When sending the data from the stream to MySQL Server, MySQL Connector/C++ will split the stream into chunks appropriate for MySQL Server and observe the `max_allowed_packet` setting currently being used.

Caution

When using `setString()` it is not possible to set `max_allowed_packet` [519] to a value large enough for the string, prior to passing it to MySQL Connector/C++. That configuration option cannot be changed within a session.

This difference with the JDBC specification ensures that MySQL Connector/C++ is not vulnerable to memory flooding attacks.

- In general, MySQL Connector/C++ works with MySQL 5.0, but it is not completely supported. Some methods may not be available when connecting to MySQL 5.0. This is because the Information Schema is used to obtain the requested information. There are no plans to improve the support for 5.0 because the current GA version of MySQL Server is 5.5. As a new product, MySQL Connector/C++ is primarily targeted at the MySQL Server GA version that was available on its release.

The following methods will throw a `sql::MethodNotImplemented` exception when you connect to MySQL earlier than 5.1.0:

- `DatabaseMetadata::getCrossReference()`
- `DatabaseMetadata::getExportedKeys()`
- MySQL Connector/C++ includes a method `Connection::getClientOption()` which is not included in the JDBC API specification. The prototype is:

```
void getClientOption(const std::string & optionName, void * optionValue)
```

The method can be used to check the value of connection properties set when establishing a database connection. The values are returned through the `optionValue` argument passed to the method with the type `void *`.

Currently, `getClientOption()` supports fetching the `optionValue` of the following options:

- `metadataUseInfoSchema`
- `defaultStatementResultType`
- `defaultPreparedStatementResultType`

The connection option `metadataUseInfoSchema` controls whether to use the `Information_Schemata` for returning the meta data of `SHOW` commands. In the case of `metadataUseInfoSchema`, interpret the `optionValue` argument as a boolean upon return.

In the case of both `defaultStatementResultType` and `defaultPreparedStatementResultType`, interpret the `optionValue` argument as an integer upon return.

The connection property can be either set when establishing the connection through the connection property map or using `void Connection::setClientOption(const std::string & optionName, const void * optionValue)` where `optionName` is assigned the value `metadataUseInfoSchema`.

Some examples are given below:

```
int defaultStmtResType;
int defaultPStmtResType;
conn->getClientOption("defaultStatementResultType", (void *) &defaultStmtResType);
conn->getClientOption("defaultPreparedStatementResultType", (void *) &defaultPStmtResType);

bool isInfoSchemaUsed;
conn->getClientOption("metadataUseInfoSchema", (void *) &isInfoSchemaUsed);
```

- MySQL Connector/C++ also supports the following methods not found in the JDBC API standard:

```
std::string MySQL_Connection::getSessionVariable(const std::string & varname)
```

```
void MySQL_Connection::setSessionVariable(const std::string & varname, const std::string & value)
```

Note that both methods are members of the `MySQL_Connection` class. The methods get and set MySQL session variables.

`setSessionVariable()` is equivalent to executing:

```
SET SESSION <varname> = <value>
```

`getSessionVariable()` is equivalent to executing the following and fetching the first return value:

```
SHOW SESSION VARIABLES LIKE "<varname>"
```

You can use “%” and other placeholders in `<varname>`, if the underlying MySQL server supports this.

- Fetching the value of a column can sometimes return different values depending on whether the call is made from a Statement or Prepared Statement. This is because the protocol used to communicate with the server differs depending on whether a Statement or Prepared Statement is used.

To illustrate this, consider the case where a column has been defined as of type `BIGINT`. The most negative `BIGINT` value is then inserted into the column. If a Statement and Prepared Statement are created that perform a `GetUInt64()` call, then the results will be different in each case. The Statement returns the maximum positive value for `BIGINT`. The Prepared Statement returns 0.

The reason for the different results is due to the fact that Statements use a text protocol, and Prepared Statements use a binary protocol. With the binary protocol in this case, a binary value is returned from the server that can be interpreted as an `int64`. In the above scenario a very large negative value was fetched with `GetUInt64()`, which fetches unsigned integers. As the large negative value cannot be sensibly converted to an unsigned value 0 is returned.

In the case of the Statement, which uses the text protocol, values are returned from the server as strings, and then converted as required. When a string value is returned from the server in the above scenario, the large negative value must be converted by the runtime library function `strtoul()`, which `GetUInt64()` calls. The behavior of `strtoul()` is dependent upon the specific runtime and host operating system, so the results can be variable. In the case given a large positive value was actually returned.

Although it is very rare, there are some cases where Statements and Prepared Statements can return different values unexpectedly, but this usually only happens in extreme cases such as the one mentioned.

- The JDBC documentation [lists many fields](#) for the `DatabaseMetaData` class. JDBC also appears to [define certain values](#) for those fields. However, MySQL Connector/C++ does not define certain values

for those fields. Internally enumerations are used and the compiler determines the values to assign to a field.

To compare a value with the field, use code such as the following, rather than making assumptions about specific values for the attribute:

```
// dbmeta is an instance of DatabaseMetaData
if (myvalue == dbmeta->attributeNoNulls) {
    ...
}
```

Usually *myvalue* will be a column from a result set holding metadata information. MySQL Connector/C++ does not guarantee that `attributeNoNulls` is 0. It can be any value.

- When programming Stored Procedures, JDBC has available an extra class, an extra abstraction layer for callable statements, the `CallableStatement` class. As this class is not present in MySQL Connector/C++, use the methods from the `Statement` and `PreparedStatement` classes to run a Stored Procedure using `CALL`.

22.4.9. MySQL Connector/C++ Known Bugs and Issues

Note

Please report bugs through [MySQL Bug System](#).

Known bugs:

None.

Known issues:

- When linking against a static library for 1.0.3 on Windows, define `CPPDBC_PUBLIC_FUNC` either in the compiler options (preferable) or with `/D "CPPCONN_PUBLIC_FUNC="`. You can also explicitly define it in your code by placing `#define CPPCONN_PUBLIC_FUNC` before the header inclusions.
- Generally speaking, C++ library binaries are less portable than C library binaries. Issues can be caused by name mangling, different Standard Template Library (STL) versions and using different compilers and linkers for linking against the libraries than were used for building the library itself.

Even a small change in the compiler version can, but does not have to, cause problems. If you obtain error messages, that you suspect are related to binary incompatibilities, build MySQL Connector/C++ from source, using the same compiler and linker that you will use to build and link your application.

Due to the variations between Linux distributions, compiler and linker versions and STL versions, it is not possible to provide binaries for each and every possible configuration. However, the MySQL Connector/C++ binary distributions contain a [README](#) file that describes the environment and settings used to build the binary versions of the libraries.

- To avoid potential crashes the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

For release notes detailing the changes in each release of Connector/C++, see [MySQL Connector/C++ Release Notes](#).

22.4.10. MySQL Connector/C++ Feature requests

You can suggest new features in the first instance by joining the mailing list or forum and talking with the developers directly. See [Section 22.4.11, “MySQL Connector/C++ Support”](#)

The following feature requests are currently being worked on:

- C++ references for `Statements`, `ResultSets`, and exceptions, are being considered, instead of pointers to heap memory. This reduces the exception handling burden for the programmer.
- Adopt STL (suggestions are welcome).
- JDBC compliance: data type interfaces and support through `ResultSet::getType()` and `PreparedStatement::bind()`. Introduce `sql::Blob`, `sql::Clob`, `sql::Date`, `sql::Time`, `sql::Timestamp`, `sql::URL`. Support `get|setBlob()`, `get|setClob()`, `get|setDate()`, `get|setTime()`, `get|setTimestamp()`, `get|setURL()`
- Add support for all C-API connection options. Improved support for `mysql_options`.
- Add connect method which supports passing options using HashMaps.
- Create Windows installer.

22.4.11. MySQL Connector/C++ Support

For general discussion of the MySQL Connector/C++ please use the [C/C++ community forum](#) or join the [MySQL Connector/C++ mailing list](#).

Bugs can be reported at the [MySQL bug Web site](#).

For release notes detailing the changes in each release of MySQL Connector/C++, see [MySQL Connector/C++ Release Notes](#).

For Licensing questions, and to purchase MySQL Products and Services, please see <http://www.mysql.com/buy-mysql/>

22.5. MySQL Connector/C

What is MySQL Connector/C?

MySQL Connector/C is a C client library for client/server communication. It is a standalone replacement for the MySQL Client Library shipped with the MySQL Server.

Why have a replacement for MySQL Client Library?

There is no need to compile or install the MySQL Server package if you need only the client library.

MySQL Connector/C does not rely on the MySQL Server release cycle, so bug fixes and new features can be distributed independently of MySQL Server releases.

MySQL Connector/C API documentation is available here [Section 22.8.3, “C API Function Descriptions”](#).

For release notes detailing the changes in each release of MySQL Connector/C, see [MySQL Connector/C Release Notes](#).

Supported platforms include:

- Windows
- Windows x64
- Linux
- Solaris
- FreeBSD
- Mac OS X
- HP-UX
- IBM AIX

22.5.1. Building MySQL Connector/C from the Source Code

Obtaining the Source Code

You can [download a tar file containing the source code](#) from the MySQL Developers site. Select the source code package from the drop down list.

The source code for development releases of the connector can be found at <http://launchpad.net/libmysql> on the Launchpad site.

The [source code for the 1.0 branch](#) is also available on the Launchpad site.

To get the code from the Launchpad site, you must have Bazaar installed. Use the command `bzr branch lp:libmysql`.

Building on Unix

Examples of supported Unix or Unix-like operating systems include:

- Solaris
- Linux
- HP-UX
- AIX
- OS X

Compiler Tools

Ideally, the native compiler tool set for the target platform is used for compilation. For example, this would be SunStudio for Solaris or aCC for HP-UX. However, the GNU tool-chain can be used across all platforms.

You also need [CMake](#) 2.6 or newer, which is available [online](#).

To Build

Change location to the top-level MySQL Connector/C source directory and use the following procedure:

1. To generate the `Makefile`, enter this command:

```
shell> cmake -G "Unix Makefiles"
```

Or, for a Debug build:

```
shell> cmake -G "Unix Makefiles" -DCMAKE_BUILD_TYPE=Debug
```

2. Build the project:

```
shell> make
```

To Install

By default, `make install` installs the MySQL Connector/C files in the `/usr/local` directory. To change this location, specify another directory when generating the `Makefile`:

```
shell> cmake -G "Unix Makefiles" -DCMAKE_INSTALL_PREFIX=/mypath
```

Now, as `root`, enter the following command to install the MySQL Connector/C libraries and tools:

```
root-shell> make install
```

At this point, all of the MySQL Connector/C files will be in place.

Building on Microsoft Windows

Older versions of Microsoft Windows are not supported. Supported versions are Windows 2000, Windows XP, Windows Vista, Windows Server 2003, or Windows Server 2008.

Compiler Tools

Microsoft Visual Studio 8 or 9 is recommended. The Express Edition of Visual Studio and other compilers might work, but are untested.

You also need `CMake` 2.6 or newer, which is available [online](#).

To Build

1. Set the environment variables for the Visual Studio toolchain. Visual Studio includes a batch file to set these for you, and installs a shortcut in the **Start** menu to open a command prompt with these variables set.
2. Change location to the top-level MySQL Connector/C source directory.

To build MySQL Connector/C using the `CMake` command-line tool, enter the following command in a command prompt window:

```
shell> cmake -G "Visual Studio 9 2008"
```

The result is a project file, `libmysql.sln`, that you can either open with Visual Studio, or build from the command line with either of these commands:

```
shell> devenv.com libmysql.sln /build Release
```

```
shell> devenv.com libmysql.sln /build RelWithDebInfo
```

For other versions of Visual Studio or `nmake` based build, run the following command:

```
shell> cmake --help
```

to check the supported generators.

To compile the Debug build, you must run set the `CMake` build type so the correct external library versions are used:

```
shell> cmake -G "Visual Studio 9 2008" -DCMAKE_BUILD_TYPE=Debug
```

Followed by:

```
shell> devenv.com libmysql.sln /build Debug
```

To Install

To create a install package you can choose between two packaging formats:

- **Zip package**

To create a Zip package, run the `cpack` command from the top-level MySQL Connector/C source directory.

- **MSI Install package**

The required tools include Windows XML Installer toolset (WIX), which is available [online](#).

To create the MSI install package, change location to the subdirectory `win` of the MySQL Connector/C source tree and generate the `Makefile`:

```
shell> cmake -G "NMake Makefiles"
```

Create the MSI install package by invoking `nmake`:

```
shell> nmake
```

Other Build Options

The following options can be used when building the MySQL Connector/C source code:

Table 22.28. Build Options for MySQL Connector/C

| Build Option | Description |
|------------------------|--|
| -DWITH_OPENSSL=1 | Enables dynamic linking to the system OpenSSL library. |
| -DWITH_EXTERNAL_ZLIB=1 | Enables dynamic linking to the system Zlib library. |

22.5.2. Testing MySQL Connector/C

To test MySQL Connector/C, you need a running MySQL server instance. Before you run the test suite, specify the following environment variables:

- `MYSQL_TEST_HOST`: The host where the MySQL server is running (default `localhost`)
- `MYSQL_TEST_USER`: The user name of the MySQL account to use
- `MYSQL_TEST_PASSWD`: The password of the MySQL account to use

- `MYSQL_TEST_PORT`: The port to connect to
- `MYSQL_TEST_SOCKET`: The socket file to connect to
- `MYSQL_TEST_DB`: The default database to use (default `test`)

To run the test suite, execute `ctest` from the command line:

```
shell> ctest
```

22.5.3. MySQL Connector/C FAQ

Questions

- [23.5.3.1: \[3033\]](#) What is the “MySQL Native C API”? What are its typical benefits and use cases?
- [23.5.3.2: \[3033\]](#) What is “libmysql”?
- [23.5.3.3: \[3033\]](#) What is “libmysqld”?
- [23.5.3.4: \[3033\]](#) What is “MySQL Connector/C”?
- [23.5.3.5: \[3033\]](#) What is the difference between “Native C API”, “libmysql”, “libmysqld” and “MySQL Connector/C”?
- [23.5.3.6: \[3034\]](#) Does MySQL Connector/C replace any of “Native C API”, “libmysql” and “libmysqld”?

Questions and Answers

23.5.3.1: What is the “MySQL Native C API”? What are its typical benefits and use cases?

MySQL Connector/C, also known as `libmysql`, or MySQL Native C API, is a standalone, C-based API and library that you can use in C applications to connect to the MySQL Server. It implements the same MySQL client API that has been in use for a decade.

It is also used as the foundation for drivers for standard database APIs such as ODBC, Perl DBI, and Python DB API.

23.5.3.2: What is “libmysql”?

`libmysql` is the name of the library that MySQL Connector/C provides.

23.5.3.3: What is “libmysqld”?

`libmysqld` is an embedded database server with the same API as MySQL Connector/C. It is included with the MySQL Server distribution.

23.5.3.4: What is “MySQL Connector/C”?

MySQL Connector/C is a standalone distribution of the `libmysql` library, which was previously only available as part of the MySQL Server distribution. The version of `libmysql` included with MySQL Connector/C and the version bundled with the server are functionally equivalent, but the cross-platform build system for MySQL Connector/C uses `CMake`.

23.5.3.5: What is the difference between “Native C API”, “libmysql”, “libmysqld” and “MySQL Connector/C”?

MySQL Connector/C and `libmysql` are the “native C API for MySQL”, and all three terms can be used interchangeably. “`libmysqld`” is the embedded version of the MySQL Server, and is included in the server distribution.

23.5.3.6: Does MySQL Connector/C replace any of “Native C API”, “`libmysql`” and “`libmysqld`”?

MySQL Connector/C contains `libmysql`, and implements a native C API. It does not include `libmysqld`, which can be found with the MySQL server distribution.

22.6. MySQL Connector/Python

MySQL Connector/Python allows Python programs to access MySQL databases, using an API that is compliant with the [Python DB API version 2.0](#). It is written in pure Python and does not have any dependencies except for the [Python Standard Library](#).

MySQL Connector/Python includes support for:

- Almost all features provided by MySQL Server up to and including MySQL Server version 5.5.
- Converting parameter values back and forth between Python and MySQL data types, for example Python `datetime` and MySQL `DATETIME`. You can turn automatic conversion on for convenience, or off for optimal performance.
- All MySQL extensions to standard SQL syntax.
- Protocol compression, which enables compressing the data stream between the client and server.
- Connections using TCP/IP sockets and on Unix using Unix sockets.
- Secure TCP/IP connections using SSL.
- Self-contained driver. Connector/Python does not require the MySQL client library or any Python modules outside the standard library.

MySQL Connector/Python supports from Python version 2.4 through 2.7, and Python 3.1 and later. Note that Connector/Python does not support the old MySQL Server authentication methods, which means that MySQL versions prior to 4.1 will not work.

For release notes detailing the changes in each release of Connector/Python, see [MySQL Connector/Python Release Notes](#).

22.6.1. Guidelines for Python Developers

The following guidelines cover aspects of developing MySQL applications that might not be immediately obvious to developers coming from a Python background:

- For security, do not hardcode the values needed to connect and log into the database in your main script. Python has the convention of a `config.py` module, where you can keep such values separate from the rest of your code.
- Python scripts often build up and tear down large data structures in memory, up to the limits of available RAM. Because MySQL often deals with data sets that are many times larger than available memory, techniques that optimize storage space and disk I/O are especially important. For example, in MySQL tables, you typically use numeric IDs rather than string-based dictionary keys, so that the key values are compact and have a predictable length. This is especially important for columns that make up the [primary key](#) for an `InnoDB` table, because those column values are duplicated within each [secondary index](#).

- Any application that accepts input must expect to handle bad data.

The bad data might be accidental, such as out-of-range values or misformatted strings. The application can use server-side checks such as [unique constraints](#) and [NOT NULL constraints](#), to keep the bad data from ever reaching the database. On the client side, use techniques such as exception handlers to report any problems and take corrective action.

The bad data might also be deliberate, representing a “SQL injection” attack. For example, input values might contain quotation marks, semicolons, % and _ wildcard characters and other characters significant in SQL statements. Validate input values to make sure they have only the expected characters. Escape any special characters that could change the intended behavior when substituted into a SQL statement. Never concatenate a user input value into a SQL statement without doing validation and escaping first. Even when accepting input generated by some other program, expect that the other program could also be hacked and be sending you incorrect or malicious data.

- Because the result sets from SQL queries can be very large, use the appropriate method to retrieve items from the result set as you loop through them. [fetchone\(\)](#) retrieves a single item, when you know the result set contains a single row. [fetchall\(\)](#) retrieves all the items, when you know the result set contains a limited number of rows that can fit comfortably into memory. [fetchmany\(\)](#) is the general-purpose method when you cannot predict the size of the result set: you keep calling it and looping through the returned items, until there are no more results to process.
- Since Python already has convenient modules such as [pickle](#) and [cPickle](#) to read and write data structures on disk, the data that you choose store in MySQL instead is likely to have special characteristics:
 - **Too large to all fit in memory at one time.** You use [SELECT](#) statements to query only the precise items you need, and [aggregate functions](#) to perform calculations across multiple items. You configure the [innodb_buffer_pool_size \[1549\]](#) option within the MySQL server to dedicate a certain amount of RAM for caching query results.
 - **Too complex to be represented by a single data structure.** You divide the data between different SQL tables. You can recombine data from multiple tables by using a [join](#) query. You make sure that related data is kept in sync between different tables by setting up [foreign key](#) relationships.
 - **Updated frequently, perhaps by multiple users simultaneously.** The updates might only affect a small portion of the data, making it wasteful to write the whole structure each time. You use the SQL [INSERT](#), [UPDATE](#), and [DELETE](#) statements to update different items concurrently, writing only the changed values to disk. You use [InnoDB](#) tables and [transactions](#) to keep write operations from conflicting with each other, and to return consistent query results even as the underlying data is being updated.
- Building in MySQL best practices for performance can help your application to scale without requiring major rewrites and architectural changes. See [Chapter 8, Optimization](#) for best practices for MySQL performance. It offers guidelines and tips for SQL tuning, database design, and server configuration.
- You can avoid reinventing the wheel by learning the MySQL SQL statements for common operations: operators to use in queries, techniques for bulk loading data, and so on. Some statements and clauses are extensions to the basic ones defined by the SQL standard. See [Section 13.2, “Data Manipulation Statements”](#), [Section 13.1, “Data Definition Statements”](#), and [Section 13.2.9, “SELECT Syntax”](#) for the main classes of statements.
- Issuing SQL statements from Python typically involves declaring very long, possibly multi-line string literals. Because string literals within the SQL statements could be enclosed by single quotation, double quotation marks, or contain either of those characters, for simplicity you can use Python's triple-quoting mechanism to enclose the entire statement. For example:

```
'''It doesn't matter if this string contains 'single'
or "double" quotes, as long as there aren't 3 in a
row.'''
```

You can use either of the ' or " characters for triple-quoting multi-line string literals.

- Many of the secrets to a fast, scalable MySQL application involve using the right syntax at the very start of your setup procedure, in the `CREATE TABLE` statements. For example, Oracle recommends the `ENGINE=INNODB` clause for most tables, and makes it the default in MySQL 5.5 and up. Using `InnoDB` tables enables transactional behavior that helps scalability of read-write workloads and offers automatic [crash recovery](#). A follow-on recommendation is to declare a numeric [primary key](#) for each table, which offers the fastest way to look up values and can act as a pointer to associated values in other tables (a [foreign key](#)). Also within the `CREATE TABLE` statement, using the most compact column data types that meet your application requirements helps performance and scalability, as the database server moves large amounts of data back and forth between memory and disk.

22.6.2. Connector/Python Versions

MySQL Connector/Python v1.0.x series went going through a series of beta releases, leading to the first generally available (GA) version 1.0.7. Any development releases prior to general availability are not supported now that the GA version is released.

The following table summarizes the available Connector/Python versions:

Table 22.29. Connector/Python Version Reference

| Connector/Python Version | MySQL Server Versions | Python Versions | Support Status for Connector |
|--------------------------|--------------------------|------------------------------------|------------------------------|
| 1.0 | 5.6, 5.5 (5.1, 5.0, 4.1) | 2.7, 2.6 (2.5, 2.4); 3.1 and later | Recommended version |

Note

MySQL server and Python versions within brackets are known to work with Connector/Python, but are not officially supported. Bugs might not get fixed for those versions.

22.6.3. Connector/Python Installation

Connector/Python runs on any platform where Python is installed. Python comes pre-installed on almost any Linux distribution or UNIX-like system such as Apple Mac OS X and FreeBSD. On Microsoft Windows systems, you can install Python using the installer found on the [Python Download website](#).

Connector/Python is a pure Python implementation of the MySQL Client/Server protocol, meaning it does not require any other MySQL client libraries or other components. It also has no third-party dependencies. If you need SSL support, verify that your Python installation has been compiled using the [OpenSSL](#) libraries.

The installation of Connector/Python is similar on every platform and follows the standard [Python Distribution Utilities](#) or [Distutils](#). Some platforms have specific packaging, for example RPM, and, when made available, the installation of these will be covered in this manual.

Python terminology regarding distributions:

- **Source Distribution** is a distribution that contains only source files and is generally platform independent.
- **Built Distribution** can be regarded as a binary package. It contains both sources and platform-independent bytecode.

22.6.3.1. Installing Connector/Python Source Distribution on Linux, UNIX, or OS X

On UNIX-like systems such as Linux distributions, Solaris, Apple Mac OS X, and FreeBSD, you can download Connector/Python as a `tar` archive from <http://dev.mysql.com/downloads/connector/python/>.

To install Connector/Python from the `.tar.gz` file, download the latest version and follow these steps:

```
shell> gunzip mysql-connector-python-1.0.6b1.tar.gz
shell> tar xf mysql-connector-python-1.0.6b1.tar
shell> cd mysql-connector-python-1.0.6b1
shell> sudo python setup.py install
```

On UNIX-like systems, Connector/Python gets installed in the default location `/prefix/lib/pythonX.Y/site-packages/`, where `prefix` is the location where Python was installed and `X.Y` is the version of Python. See [How installation works](#) in the Python manual.

If you are not sure where Connector/Python was installed, do the following to retrieve the location:

```
shell> python
>>> from distutils.sysconfig import get_python_lib

>>> print get_python_lib()           # Python v2.x
/Library/Python/2.7/site-packages

>>> print(get_python_lib())         # Python v3.x
/Library/Frameworks/Python.framework/Versions/3.1/lib/python3.1/site-packages
```

Note

The above example shows the default installation location on Mac OS X 10.7.

22.6.3.2. Installing Connector/Python Source Distribution on Microsoft Windows

On Microsoft Windows systems, you can download Connector/Python as a `zip` archive from <http://dev.mysql.com/downloads/connector/python/>.

Make sure that the Python executable is available in the Windows `%PATH%` setting. For more information about installation and configuration of Python on Windows, see the section [Using Python on Windows](#) in the Python documentation.

To install Connector/Python from the `.zip` file, download the latest version and follow these steps:

1. Unpack the downloaded `zip` archive into a directory of your choice. For example, into the folder `C:\mysql-connector\`. Use the appropriate unzip command for your system, for example, `unzip`, `pkunzip`, and so on.
2. Start a console window (or a DOS window) and change to the folder where you unpacked the Connector/Python `zip` archive.

```
shell> cd C:\mysql-connector\
```

3. Once inside the Connector/Python folder, do the following:

```
shell> python setup.py install
```

On Windows, Connector/Python gets installed in the default location `C:\PythonX.Y\Lib\site-packages\` where `X.Y` is the Python version you used to install the connector.

If you are not sure where Connector/Python ended up, do the following to retrieve the location where packages get installed:

```
shell> python
>>> from distutils.sysconfig import get_python_lib
>>> print get_python_lib()           # Python v2.x
>>> print(get_python_lib())         # Python v3.x
```

22.6.3.3. Verifying Your Connector/Python Installation

To test that your Connector/Python installation is working and is able to connect to a MySQL database server, you can run a very simple program where you substitute the login credentials and host information of the MySQL server. See [Section 22.6.4.1, “Connecting to MySQL Using Connector/Python”](#) for an example.

22.6.4. Connector/Python Coding Examples

These coding examples illustrate how to develop Python applications and scripts which connect to a MySQL Server using MySQL Connector/Python.

22.6.4.1. Connecting to MySQL Using Connector/Python

The `connect()` constructor is used for creating a connection to the MySQL server and returns a `MySQLConnection` object.

The following example shows how to connect to the MySQL server:

```
import mysql.connector

cnx = mysql.connector.connect(user='scott', password='tiger',
                              host='127.0.0.1',
                              database='employees')

cnx.close()
```

See [Section 22.6.6, “Connector/Python Connection Arguments”](#) for all possible connection arguments.

It is also possible to create connection objects using the `connection.MySQLConnection()` class. Both methods, using the `connect()` constructor, or the class directly, are valid and functionally equal, but using `connector()` is preferred and will be used in most examples in this manual.

To handle connection errors, use the `try` statement and catch all errors using the `errors.Error` exception:

```
import mysql.connector
from mysql.connector import errorcode

try:
    cnx = mysql.connector.connect(user='scott',
                                  database='testt')
except mysql.connector.Error as err:
    if err.errno == errorcode.ER_ACCESS_DENIED_ERROR:
        print("Something is wrong your username or password")
    elif err.errno == errorcode.ER_BAD_DB_ERROR:
```

```

    print("Database does not exists")
else:
    print(err)
else:
    cnx.close()

```

If you have lots of connection arguments, it's best to keep them in a dictionary and use the `**`-operator. Here is an example:

```

import mysql.connector

config = {
    'user': 'scott',
    'password': 'tiger',
    'host': '127.0.0.1',
    'database': 'employees',
    'raise_on_warnings': True,
}

cnx = mysql.connector.connect(**config)

cnx.close()

```

22.6.4.2. Creating Tables Using Connector/Python

All **DDL** (Data Definition Language) statements are executed using a handle structure known as a cursor. The following examples show how to create the tables of the `employees` database. You will need them for the other examples.

In a MySQL server, tables are very long-lived objects, and are often accessed by multiple applications written in different languages. You might typically work with tables that are already set up, rather than creating them within your own application. Avoid setting up and dropping tables over and over again, as that is an expensive operation. The exception is **temporary tables**, which can be created and dropped quickly within an application.

```

from __future__ import print_function

import mysql.connector
from mysql.connector import errorcode

DB_NAME = 'employees'

TABLES = {}
TABLES['employees'] = (
    "CREATE TABLE `employees` ("
    "  `emp_no` int(11) NOT NULL AUTO_INCREMENT,"
    "  `birth_date` date NOT NULL,"
    "  `first_name` varchar(14) NOT NULL,"
    "  `last_name` varchar(16) NOT NULL,"
    "  `gender` enum('M','F') NOT NULL,"
    "  `hire_date` date NOT NULL,"
    "  PRIMARY KEY (`emp_no`)"
    ") ENGINE=InnoDB")

TABLES['departments'] = (
    "CREATE TABLE `departments` ("
    "  `dept_no` char(4) NOT NULL,"
    "  `dept_name` varchar(40) NOT NULL,"
    "  PRIMARY KEY (`dept_no`), UNIQUE KEY `dept_name` (`dept_name`)"
    ") ENGINE=InnoDB")

TABLES['salaries'] = (
    "CREATE TABLE `salaries` ("
    "  `emp_no` int(11) NOT NULL,"

```

```

" `salary` int(11) NOT NULL,"
" `from_date` date NOT NULL,"
" `to_date` date NOT NULL,"
" PRIMARY KEY (`emp_no`,`from_date`), KEY `emp_no` (`emp_no`),"
" CONSTRAINT `salaries_ibfk_1` FOREIGN KEY (`emp_no`) "
" REFERENCES `employees` (`emp_no`) ON DELETE CASCADE"
") ENGINE=InnoDB"

TABLES['dept_emp'] = (
"CREATE TABLE `dept_emp` ("
" `emp_no` int(11) NOT NULL,"
" `dept_no` char(4) NOT NULL,"
" `from_date` date NOT NULL,"
" `to_date` date NOT NULL,"
" PRIMARY KEY (`emp_no`,`dept_no`), KEY `emp_no` (`emp_no`),"
" KEY `dept_no` (`dept_no`),"
" CONSTRAINT `dept_emp_ibfk_1` FOREIGN KEY (`emp_no`) "
" REFERENCES `employees` (`emp_no`) ON DELETE CASCADE,"
" CONSTRAINT `dept_emp_ibfk_2` FOREIGN KEY (`dept_no`) "
" REFERENCES `departments` (`dept_no`) ON DELETE CASCADE"
") ENGINE=InnoDB"

TABLES['dept_manager'] = (
" CREATE TABLE `dept_manager` ("
" `dept_no` char(4) NOT NULL,"
" `emp_no` int(11) NOT NULL,"
" `from_date` date NOT NULL,"
" `to_date` date NOT NULL,"
" PRIMARY KEY (`emp_no`,`dept_no`),"
" KEY `emp_no` (`emp_no`),"
" KEY `dept_no` (`dept_no`),"
" CONSTRAINT `dept_manager_ibfk_1` FOREIGN KEY (`emp_no`) "
" REFERENCES `employees` (`emp_no`) ON DELETE CASCADE,"
" CONSTRAINT `dept_manager_ibfk_2` FOREIGN KEY (`dept_no`) "
" REFERENCES `departments` (`dept_no`) ON DELETE CASCADE"
") ENGINE=InnoDB"

TABLES['titles'] = (
"CREATE TABLE `titles` ("
" `emp_no` int(11) NOT NULL,"
" `title` varchar(50) NOT NULL,"
" `from_date` date NOT NULL,"
" `to_date` date DEFAULT NULL,"
" PRIMARY KEY (`emp_no`,`title`,`from_date`), KEY `emp_no` (`emp_no`),"
" CONSTRAINT `titles_ibfk_1` FOREIGN KEY (`emp_no`) "
" REFERENCES `employees` (`emp_no`) ON DELETE CASCADE"
") ENGINE=InnoDB"

```

The above code shows how we are storing the `CREATE` statements in a Python dictionary called `TABLES`. We also define the database in a global variable called `DB_NAME`, which allows you to easily use a different schema.

```

cnx = mysql.connector.connect(user='scott')
cursor = cnx.cursor()

```

A single MySQL server can contain multiple [databases](#). Typically, you specify the database to switch to when connecting to the MySQL server. This example does not connect to the database upon connection, so that it can make sure the database exists, and create it if not.

```

def create_database(cursor):
    try:
        cursor.execute(
            "CREATE DATABASE {} DEFAULT CHARACTER SET 'utf8'".format(DB_NAME))
    except mysql.connector.Error as err:
        print("Failed creating database: {}".format(err))
        exit(1)

```

```

try:
    cnx.database = DB_NAME
except mysql.connector.Error as err:
    if err.errno == errorcode.ER_BAD_DB_ERROR:
        create_database(cursor)
        cnx.database = DB_NAME
    else:
        print(err)
        exit(1)

```

We first try to change to a particular database using the `database` property of the connection object `cnx`. If there is an error, we examine the error number to check if the database does not exist. If so, we call the `create_database` function to create it for us.

On any other error, the application exits and displays the error message.

```

for name, ddl in TABLES.iteritems():
    try:
        print("Creating table {}: ".format(name), end='')
        cursor.execute(ddl)
    except mysql.connector.Error as err:
        if err.errno == errorcode.ER_TABLE_EXISTS_ERROR:
            print("already exists.")
        else:
            print(err.errmsg)
    else:
        print("OK")

cursor.close()
cnx.close()

```

After we successfully created or changed to the target database, we create the tables by iterating over the items of the `TABLES` dictionary.

We handle the error when the table already exists by simply notifying the user that it was already there. Other errors are printed, but we simply continue creating tables. (We show how to handle the “table already exists” condition for illustration purposes. In a real application, we would typically avoid the error condition entirely by using the `IF NOT EXISTS` clause of the `CREATE TABLE` statement.)

The output would be something like this:

```

Creating table employees: already exists.
Creating table salaries: already exists.
Creating table titles: OK
Creating table departments: already exists.
Creating table dept_manager: already exists.
Creating table dept_emp: already exists.

```

To populate the employees tables, use the dump files of the [Employee Sample Database](#). Note that you only need the data dump files that you will find in an archive named like `employees_db-dump-files-1.0.5.tar.bz2`. After downloading the dump files, do the following from the command line, adding connection options to the `mysql` commands if necessary:

```

shell> tar xzf employees_db-dump-files-1.0.5.tar.bz2
shell> cd employees_db
shell> mysql employees < load_employees.dump
shell> mysql employees < load_titles.dump
shell> mysql employees < load_departments.dump
shell> mysql employees < load_salaries.dump
shell> mysql employees < load_dept_emp.dump
shell> mysql employees < load_dept_manager.dump

```

22.6.4.3. Inserting Data Using Connector/Python

Inserting or updating data is also done using the handler structure known as a cursor. When you use a transactional storage engine such as [InnoDB](#) (which is the default in MySQL 5.5 and later), you must [commit](#) the data after a sequence of [INSERT](#), [DELETE](#), and [UPDATE](#) statements.

In this example we show how to insert new data. The second [INSERT](#) depends on the value of the newly created [primary key](#) of the first. We are also demonstrating how to use extended formats. The task is to add a new employee starting to work tomorrow with a salary set to 50000.

Note

The following example uses tables created in the example [Section 22.6.4.2, “Creating Tables Using Connector/Python”](#). The [AUTO_INCREMENT](#) column option for the primary key of the [employees](#) table is important to ensure reliable, easily searchable data.

```
from __future__ import print_function
from datetime import date, datetime, timedelta
import mysql.connector

cnx = mysql.connector.connect(user='scott', database='employees')
cursor = cnx.cursor()

tomorrow = datetime.now().date() + timedelta(days=1)

add_employee = ("INSERT INTO employees "
               "(first_name, last_name, hire_date, gender, birth_date) "
               "VALUES (%s, %s, %s, %s, %s)")
add_salary = ("INSERT INTO salaries "
              "(emp_no, salary, from_date, to_date) "
              "VALUES (%(emp_no)s, %(salary)s, %(from_date)s, %(to_date)s)")

data_employee = ('Geert', 'Vanderkelen', tomorrow, 'M', date(1977, 6, 14))

# Insert new employee
cursor.execute(add_employee, data_employee)
emp_no = cursor.lastrowid

# Insert salary information
data_salary = {
    'emp_no': emp_no,
    'salary': 50000,
    'from_date': tomorrow,
    'to_date': date(9999, 1, 1),
}
cursor.execute(add_salary, data_salary)

# Make sure data is committed to the database
cnx.commit()

cursor.close()
cnx.close()
```

We first open a connection to the MySQL server and store the [connection object](#) in the variable `cnx`. We then create a new cursor, by default a [MySQLCursor](#) object, using the connection's `cursor()` method.

We could calculate tomorrow by calling a database function, but for clarity we do it in Python using the [datetime](#) module.

Both [INSERT](#) statements are stored in the variables called `add_employee` and `add_salary`. Note that the second [INSERT](#) statement uses extended Python format codes.

The information of the new employee is stored in the tuple `data_employee`. The query to insert the new employee is executed and we retrieve the newly inserted value for the column `emp_no` using the `lastrowid` property of the cursor object.

Next, we insert the new salary for the new employee. We are using the `emp_no` variable in the dictionary holding the data. This dictionary is passed to the `execute()` method of the cursor object.

Since by default Connector/Python turns `autocommit` off, and MySQL 5.5 and later uses transactional `InnoDB` tables by default, it is necessary to commit your changes using the connection's `commit()` method. You could also `roll back` using the `rollback()` method.

22.6.4.4. Querying Data Using Connector/Python

The following example shows how to `query` data using a cursor created using the connection's `cursor()` method. The data returned is formatted and printed on the console.

The task is to select all employees hired in the year 1999 and print their names with their hire date to the console.

```
import datetime
import mysql.connector

cnx = mysql.connector.connect(user='scott', database='employees')
cursor = cnx.cursor()

query = ("SELECT first_name, last_name, hire_date FROM employees "
        "WHERE hire_date BETWEEN %s AND %s")

hire_start = datetime.date(1999, 1, 1)
hire_end = datetime.date(1999, 12, 31)

cursor.execute(query, (hire_start, hire_end))

for (first_name, last_name, hire_date) in cursor:
    print("{} , {} was hired on {:%d %b %Y}".format(
        last_name, first_name, hire_date))

cursor.close()
cnx.close()
```

We first open a connection to the MySQL server and store the `connection object` in the variable `cnx`. We then create a new cursor, by default a `MySQLCursor` object, using the connection's `cursor()` method.

In the preceding example, we store the `SELECT` statement in the variable `query`. Note that we are using unquoted `%s`-markers where dates should have been. Connector/Python converts `hire_start` and `hire_end` from Python types to a data type that MySQL understands and adds the required quotes. In this case, it replaces the first `%s` with `'1999-01-01'`, and the second with `'1999-12-31'`.

We then execute the operation stored in the `query` variable using the `execute()` method. The data used to replace the `%s`-markers in the query is passed as a tuple: `(hire_start, hire_end)`.

After executing the query, the MySQL server is ready to send the data. The result set could be zero rows, one row, or 100 million rows. Depending on the expected volume, you can use different techniques to process this result set. In this example, we use the `cursor` object as an iterator. The first column in the row will be stored in the variable `first_name`, the second in `last_name`, and the third in `hire_date`.

We print the result, formatting the output using Python's built-in `format()` function. Note that `hire_date` was converted automatically by Connector/Python to a Python `datetime.date` object. This means that we can easily format the date in a more human-readable form.

The output should be something like this:

```
..
Wilharm, LiMin was hired on 16 Dec 1999
Wielonsky, Lalit was hired on 16 Dec 1999
Kamble, Dannz was hired on 18 Dec 1999
DuBourdieu, Zhongwei was hired on 19 Dec 1999
Fujisawa, Rosita was hired on 20 Dec 1999
..
```

22.6.5. Connector/Python Tutorials

These tutorials illustrate how to develop Python applications and scripts that connect to a MySQL database server using MySQL Connector/Python.

22.6.5.1. Tutorial: Raise employee's salary using a buffering cursor

The following example script will give a long-overdue raise effective tomorrow to all employees who joined in the year 2000 and are still with the company.

We are using buffered cursors to iterate through the selected employees. This way we do not have to fetch the rows in a new variables, but can instead use the cursor as an iterator.

Note that the script is an example; there are other ways of doing this simple task.

```
from __future__ import print_function

from decimal import Decimal
from datetime import datetime, date, timedelta

import mysql.connector

# Connect with the MySQL Server
cnx = mysql.connector.connect(user='scott', database='employees')

# Get two buffered cursors
curA = cnx.cursor(buffered=True)
curB = cnx.cursor(buffered=True)

# Query to get employees who joined in a period defined by two dates
query = (
    "SELECT s.emp_no, salary, from_date, to_date FROM employees AS e "
    "LEFT JOIN salaries AS s USING (emp_no) "
    "WHERE to_date = DATE('9999-01-01') "
    "AND e.hire_date BETWEEN DATE(%s) AND DATE(%s)")

# UPDATE and INSERT statements for the old and new salary
update_old_salary = (
    "UPDATE salaries SET to_date = %s "
    "WHERE emp_no = %s AND from_date = %s")
insert_new_salary = (
    "INSERT INTO salaries (emp_no, from_date, to_date, salary) "
    "VALUES (%s, %s, %s, %s)")

# Select the employees getting a raise
curA.execute(query, (date(2000, 1, 1), date(2001, 1, 1)))

# Iterate through the result of curA
for (emp_no, salary, from_date, to_date) in curA:

    # Update the old and insert the new salary
    new_salary = int(round(salary * Decimal('1.15')))
    curB.execute(update_old_salary, (tomorrow, emp_no, from_date))
    curB.execute(insert_new_salary,
```

```
(emp_no, tomorrow, date(9999, 1, 1), new_salary))

# Commit the changes
cnx.commit()

cnx.close()
```

22.6.6. Connector/Python Connection Arguments

The following lists the arguments which can be used to initiate a connection with the MySQL server using either:

- Function `mysql.connector.connect()`
- Class `mysql.connector.MySQLConnection()`

Table 22.30. Connection Arguments for Connector/Python

| Argument Name | Default | Description |
|---|-----------------|--|
| <code>user</code> (<code>username*</code>) | | The username used to authenticate with the MySQL Server. |
| <code>password</code> (<code>passwd*</code>) | | The password to authenticate the user with the MySQL Server. |
| <code>database</code> (<code>db*</code>) | | Database name to use when connecting with the MySQL Server. |
| <code>host</code> | 127.0.0.1 | Hostname or IP address of the MySQL Server. |
| <code>port</code> | 3306 | TCP/IP port of the MySQL Server. Must be an integer. |
| <code>unix_socket</code> | | The location of the Unix socket file. |
| <code>use_unicode</code> | True | Whether to use Unicode or not. |
| <code>charset</code> | utf8 | Which MySQL character set to use. |
| <code>collation</code> | utf8_general_ci | Which MySQL collation to use. |
| <code>autocommit</code> | False | Whether to autocommit transactions. |
| <code>time_zone</code> | | Set the <code>time_zone</code> session variable at connection. |
| <code>sql_mode</code> | | Set the <code>sql_mode</code> session variable at connection. |
| <code>get_warnings</code> | False | Whether to fetch warnings. |
| <code>raise_on_warnings</code> | False | Whether to raise an exception on warnings. |
| <code>connection_timeout</code> (<code>connect_timeout*</code>) | | Timeout for the TCP and Unix socket connections. |
| <code>client_flags</code> | | MySQL client flags. |
| <code>buffered</code> | False | Whether cursor object fetches the result immediately after executing query. |
| <code>raw</code> | False | Whether MySQL results are returned as-is, rather than converted to Python types. |
| <code>ssl_ca</code> | | File containing the SSL certificate authority. |
| <code>ssl_cert</code> | | File containing the SSL certificate file. |
| <code>ssl_key</code> | | File containing the SSL key. |
| <code>dsn</code> | | Not supported (raises <code>NotSupportedError</code> when used). |

* Synonymous argument name, available only for compatibility with other Python MySQL drivers. Oracle recommends not to use these alternative names.

Authentication with MySQL will use `username` and `password`. Note that MySQL Connector/Python does not support the old, insecure password protocols of MySQL versions prior to 4.1.

When the `database` parameter is given, the current database is set to the given value. To later change the database, execute the MySQL `USE` command or set the `database` property of the `MySQLConnection` instance.

By default, Connector/Python tries to connect to a MySQL server running on `localhost` using TCP/IP. The `host` argument defaults to IP address 127.0.0.1 and `port` to 3306. Unix sockets are supported by setting `unix_socket`. Named pipes on the Windows platform are not supported.

Strings coming from MySQL are by default returned as Python Unicode literals. To change this behavior, set `use_unicode` to `False`. You can change the character setting for the client connection through the `charset` argument. To change the character set after connecting to MySQL, set the `charset` property of the `MySQLConnection` instance. This technique is preferred over using the MySQL `SET NAMES` statement directly. Similar to the `charset` property, you can set the `collation` for the current MySQL session.

Transactions are not automatically committed; call the `commit()` method of the `MySQLConnection` instance within your application after doing a set of related insert, update, and delete operations. For data consistency and high throughput for write operations, it is best to leave the `autocommit` configuration option turned off when using `InnoDB` or other transactional tables.

The time zone can be set per connection using the `time_zone` argument. This is useful if the MySQL server is set, for example, to UTC and `TIMESTAMP` values should be returned by MySQL converted to the `PST` time zone.

MySQL supports so called SQL Modes, which will change the behavior of the server globally or per connection. For example, to have warnings raised as errors, set `sql_mode` to `TRADITIONAL`. For more information, see [Section 5.1.7, “Server SQL Modes”](#).

Warnings generated by queries are fetched automatically when `get_warnings` is set to `True`. You can also immediately raise an exception by setting `raise_on_warnings` to `True`. Consider using the MySQL `sql_mode` setting for turning warnings into errors.

To set a timeout value for connections, use `connection_timeout`.

MySQL uses `client flags` to enable or disable features. Using the `client_flags` argument, you have control of what is set. To find out what flags are available, use the following:

```
from mysql.connector.constants import ClientFlag
print '\n'.join(ClientFlag.get_full_info())
```

If `client_flags` is not specified (that is, it is zero), defaults are used for MySQL v4.1 and later. If you specify an integer greater than 0, make sure all flags are set. A better way to set and unset flags is to use a list. For example, to set `FOUND_ROWS`, but disable the default `LONG_FLAG`:

```
flags = [ClientFlag.FOUND_ROWS, -ClientFlag.LONG_FLAG]
mysql.connector.connect(client_flags=flags)
```

By default, MySQL Connector/Python does not buffer or pre-fetch results. This means that after a query is executed, your program is responsible of fetching the data. This avoids using excessive memory when queries return large result sets. If you know that the result set is small enough to handle all at once, fetching the results immediately by setting `buffered` to `True`. It is also possible to set this per cursor (see cursor manual).

MySQL types will be converted automatically to Python types. For example, a `DATETIME` column becomes a `datetime.datetime` object. When conversion should be done differently, for example to get better performance, set `raw` to `True`.

Using SSL connections is possible when your [Python installation supports SSL](#), that is, when it is compiled against the OpenSSL libraries. When you provide the arguments `ssl_ca`, `ssl_key` and `ssl_cert`, the connection switches to SSL. You can use this in combination with the `compressed` argument set to `True`.

`passwd`, `db` and `connect_timeout` are valid for compatibility with other MySQL interfaces and are respectively the same as `password`, `database` and `connection_timeout`. The latter take precedence. Data source name syntax or `dsn` is not used; if specified, it raises a `NotSupportedError` exception.

22.6.7. Connector/Python API Reference

This section contains the public API reference of Connector/Python. Although valid for both Python 2 and Python 3, examples should be considered working for Python 2.7, and Python 3.1 and greater.

The following overview shows the `mysql.connector` package with its modules. Currently, only the most useful modules, classes and functions for end users are documented.

```
mysql.connector
  errorcode
  errors
  connection
  constants
  conversion
  cursor
  dbapi
  locales
    eng
      client_error
  protocol
  utils
```

22.6.7.1. Errors and Exceptions

The `mysql.connector.errors` module defines exception classes for errors and warnings raised by MySQL Connector/Python. Most classes defined in this module are available when you import `mysql.connector`.

The exception classes defined in this module follow mostly the Python Database Specification v2.0 (PEP-249). For some MySQL client or server errors it is not always clear which exception to raise. It is good to discuss whether an error should be reclassified by opening a bug report.

MySQL Server errors are mapped with Python exception based on their SQLState (see [Section C.3, "Server Error Codes and Messages"](#)). The following list shows the `SQLState` classes and the exception Connector/Python will raise. It is, however, possible to redefine which exception is raised for each server error. Note that the default exception is `DatabaseError`.

- `02`: `DataError`
- `07`: `DatabaseError`
- `08`: `OperationalError`
- `0A`: `NotSupportedError`
- `21`: `DataError`

- [22](#): `DataError`
- [23](#): `IntegrityError`
- [24](#): `ProgrammingError`
- [25](#): `ProgrammingError`
- [26](#): `ProgrammingError`
- [27](#): `ProgrammingError`
- [28](#): `ProgrammingError`
- [2A](#): `ProgrammingError`
- [2B](#): `DatabaseError`
- [2C](#): `ProgrammingError`
- [2D](#): `DatabaseError`
- [2E](#): `DatabaseError`
- [33](#): `DatabaseError`
- [34](#): `ProgrammingError`
- [35](#): `ProgrammingError`
- [37](#): `ProgrammingError`
- [3C](#): `ProgrammingError`
- [3D](#): `ProgrammingError`
- [3F](#): `ProgrammingError`
- [40](#): `InternalError`
- [42](#): `ProgrammingError`
- [44](#): `InternalError`
- [HZ](#): `OperationalError`
- [XA](#): `IntegrityError`
- [0K](#): `OperationalError`
- [HY](#): `DatabaseError`

22.6.7.1.1. Module `errorcode`

This module contains both MySQL server and client error codes defined as module attributes with the error number as value. Using error codes instead of error numbers could make reading the source code a bit easier.

```
>>> from mysql.connector import errorcode
```

```
>>> errorcode.ER_BAD_TABLE_ERROR
1051
```

See [Section C.3, “Server Error Codes and Messages”](#) and [Section C.4, “Client Error Codes and Messages”](#).

22.6.7.1.2. Exception `errors.Error`

This exception is the base class for all other exceptions in the `errors` module. It can be used to catch all errors in a single `except` statement.

The following example shows how we could catch syntax errors:

```
import mysql.connector
try:
    cnx = mysql.connector.connect(user='scott', database='employees')
    cursor = cnx.cursor()
    cursor.execute("SELECT * FORM employees") # Syntax error in query
    cnx.close()
except mysql.connector.Error as err:
    print("Something went wrong: {}".format(err))
```

Initializing the exception supports a few optional arguments, namely `msg`, `errno`, `values` and `sqlstate`. All of them are optional and default to `None`. `errors.Error` is internally used by Connector/Python to raise MySQL client and server errors and should not be used by your application to raise exceptions.

The following examples show the result when using no or a combination of the arguments:

```
>>> from mysql.connector.errors import Error
>>> str(Error())
'Unknown error'

>>> str(Error("Oops! There was an error."))
'Oops! There was an error.'

>>> str(Error(errno=2006))
'2006: MySQL server has gone away'

>>> str(Error(errno=2002, values=('/tmp/mysql.sock', 2)))
'2002: Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)'

>>> str(Error(errno=1146, sqlstate='42S02', msg="Table 'test.spam' doesn't exist"))
'1146 (42S02): Table 'test.spam' doesn't exist'
```

The example which uses error number 1146 is used when Connector/Python receives an error packet from the MySQL Server. The information is parsed and passed to the `Error` exception as shown.

Each exception subclassing from `Error` can be initialized using the above mentioned arguments. Additionally, each instance has the attributes `errno`, `msg` and `sqlstate` which can be used in your code.

The following example shows how to handle errors when dropping a table which does not exist (when you do not want to use the `IF EXISTS` clause):

```
import mysql.connector
from mysql.connector import errorcode

cnx = mysql.connector.connect(user='scott', database='test')
try:
    cur.execute("DROP TABLE spam")
except mysql.connector.Error as err:
    if err.errno == errorcode.ER_BAD_TABLE_ERROR:
        print("Creating table spam")
```

```
else:  
    raise
```

`errors.Error` is a subclass of the Python `StandardError`.

22.6.7.1.3. Exception `errors.Warning`

This exception is used for reporting important warnings, however, Connector/Python does not use it. It is included to be compliant with the Python Database Specification v2.0 (PEP-249).

Consider using either more strict [Server SQL Modes](#) or the `raise_on_warnings` connection argument to make Connector/Python raise errors when your queries produce warnings.

`errors.Warning` is a subclass of the Python `StandardError`.

22.6.7.1.4. Exception `errors.InterfaceError`

This exception is raised for errors originating from Connector/Python itself, not related to the MySQL server.

`errors.InterfaceError` is a subclass of `errors.Error`.

22.6.7.1.5. Exception `errors.DatabaseError`

This exception is the default for any MySQL error which does not fit the other exceptions.

`errors.DatabaseError` is a subclass of `errors.Error`.

22.6.7.1.6. Exception `errors.InternalError`

This exception is raised when the MySQL server encounters an internal error, for example, when a deadlock occurred.

`errors.InternalError` is a subclass of `errors.DatabaseError`.

22.6.7.1.7. Exception `errors.OperationalError`

This exception is raised for errors which are related to MySQL's operations. For example, too many connections, a hostname could not be resolved, bad handshake, server is shutting down, communication errors, and so on.

`errors.OperationalError` is a subclass of `errors.DatabaseError`.

22.6.7.1.8. Exception `errors.ProgrammingError`

This exception is raised on programming errors, for example when you have a syntax error in your SQL or a table was not found.

The following example shows how to handle syntax errors:

```
try:  
    cursor.execute("CREATE DESK t1 (id int, PRIMARY KEY (id))")  
except mysql.connector.ProgrammingError as err:  
    if err.errno == errorcode.ER_SYNTAX_ERROR:  
        print("Check your syntax!")  
    else:  
        print("Error: {}".format(err))
```

`errors.ProgrammingError` is a subclass of `errors.DatabaseError`.

22.6.7.1.9. Exception `errors.IntegrityError`

This exception is raised when the relational integrity of the data is affected. For example, a duplicate key was inserted or a foreign key constraint would fail.

The following example shows a duplicate key error raised as `IntegrityError`:

```
cursor.execute("CREATE TABLE t1 (id int, PRIMARY KEY (id))")
try:
    cursor.execute("INSERT INTO t1 (id) VALUES (1)")
    cursor.execute("INSERT INTO t1 (id) VALUES (1)")
except mysql.connector.IntegrityError as err:
    print("Error: {}".format(err))
```

`errors.IntegrityError` is a subclass of `errors.DatabaseError`.

22.6.7.1.10. Exception `errors.DataError`

This exception is raised when there were problems with the data. Examples are a column set to NULL when it can not, out of range values for a column, division by zero, column count does not match value count, and so on.

`errors.DataError` is a subclass of `errors.DatabaseError`.

22.6.7.1.11. Exception `errors.NotSupportedError`

This exception is raised in case some feature was used but not supported by the version of MySQL which returned the error. It is also raised when using functions or statements which are not supported by stored routines.

`errors.NotSupportedError` is a subclass of `errors.DatabaseError`.

22.6.7.1.12. Function `errors.custom_error_exception(error=None, exception=None)`

This function defines custom exceptions for MySQL server errors and returns current customizations.

If `error` is a MySQL Server error number, then you have to pass also the `exception` class. The `error` argument can also be a dictionary in which case the key is the server error number, and value the class of the exception to be raised.

To reset the customizations, simply supply an empty dictionary.

```
import mysql.connector
from mysql.connector import errorcode

# Server error 1028 should raise a DatabaseError
mysql.connector.custom_error_exception(1028, mysql.connector.DatabaseError)

# Or using a dictionary:
mysql.connector.custom_error_exception({
    1028: mysql.connector.DatabaseError,
    1029: mysql.connector.OperationalError,
})

# To reset, pass an empty dictionary:
mysql.connector.custom_error_exception({})
```

22.6.7.2. Class `connection.MySQLConnection`

The `MySQLConnection` class is used to open and manage a connection to a MySQL server. It also used to send commands and SQL queries and read result.

22.6.7.2.1. Constructor `connection.MySQLConnection(**kwargs)`

The `MySQLConnection` constructor initializes the attributes and when at least one argument is passed, it tries to connect with the MySQL server.

For a complete list of arguments, see [Section 22.6.6, “Connector/Python Connection Arguments”](#).

22.6.7.2.2. Method `MySQLConnection.close()`

See [`disconnect\(\)`](#).

Returns a tuple.

22.6.7.2.3. Method `MySQLConnection.config(**kwargs)`

Allows to configure a `MySQLConnection` instance after it was instantiated. See [Section 22.6.6, “Connector/Python Connection Arguments”](#) for a complete list of possible arguments.

You could use the `config()` method to change, for example, the username and call `reconnect()`.

```
cnx = MySQLConnection(user='joe', database='test')
# Connected as 'joe'
cnx.config(user='jane')
cnx.reconnect()
# Now connected as 'jane'
```

22.6.7.2.4. Method `MySQLConnection.connect(**kwargs)`

This method sets up the connection to the MySQL server. If no arguments are given, it uses the already configured or default values. See [Section 22.6.6, “Connector/Python Connection Arguments”](#) for a complete list of possible arguments.

22.6.7.2.5. Method `MySQLConnection.commit()`

This method sends the `COMMIT` command to the MySQL server, committing the current transaction. Since by default, Connector/Python does not auto commit, it is important to call this method after every transaction which updates data for tables using transactional storage engines.

See the [`rollback\(\)`](#) method for rolling back transactions.

```
>>> cursor.execute("INSERT INTO employees (first_name) VALUES (%s)", ('Jane'))
>>> cnx.commit()
```

22.6.7.2.6. Method `MySQLConnection.cursor(buffered=None, raw=None, cursor_class=None)`

This method returns a `MySQLCursor()` object, or a subclass of it depending the passed arguments.

When `buffered` is `True`, the cursor will fetch all rows after the operation is executed. This is useful when queries return small result sets. Setting `raw` will skip the conversion from MySQL data types to Python types when fetching rows. `Raw` is usually used when you want to have more performance and/or you want to do the conversion yourself.

The `cursor_class` argument can be used to pass a class to use for instantiating a new cursor. It has to be a subclass of `cursor.CursorBase`.

The returned object depends on the combination of the `buffered` and `raw` arguments.

- If not buffered and not raw: `cursor.MySQLCursor`
- If buffered and not raw: `cursor.MySQLCursorBuffered`
- If buffered and raw: `cursor.MySQLCursorBufferedRaw`
- If not buffered and raw: `cursor.MySQLCursorRaw`

Returns a `CursorBase` instance.

22.6.7.2.7. Method `MySQLConnection.cmd_change_user(username='', password='', database='', charset=33)`

Changes the user using `username` and `password`. It also causes the specified `database` to become the default (current) database. It is also possible to change the character set using the `charset` argument.

Returns a dictionary containing the OK packet information.

22.6.7.2.8. Method `MySQLConnection.cmd_debug()`

Instructs the server to write some debug information to the log. For this to work, the connected user must have the `SUPER` privilege.

Returns a dictionary containing the OK packet information.

22.6.7.2.9. Method `MySQLConnection.cmd_init_db(database)`

This method makes specified database the default (current) database. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

Returns a dictionary containing the OK packet information.

22.6.7.2.10. Method `MySQLConnection.cmd_ping()`

Checks whether the connection to the server is working.

This method is not to be used directly. Use `ping()` or `is_connected()` instead.

Returns a dictionary containing the OK packet information.

22.6.7.2.11. Method `MySQLConnection.cmd_process_info()`

This method raises the `NotSupportedError` exception. Instead, use the `SHOW PROCESSLIST` statement or query the tables found in the database `INFORMATION_SCHEMA`.

22.6.7.2.12. Method `MySQLConnection.cmd_process_kill(mysql_pid)`

Asks the server to kill the thread specified by `mysql_pid`. Although still available, it's better to use the SQL `KILL` command.

Returns a dictionary containing the OK packet information.

The following two lines do the same:

```
>>> cnx.cmd_process_kill(123)
>>> cnx.cmd_query('KILL 123')
```

22.6.7.2.13. Method `MySQLConnection.cmd_quit()`

This method sends the `QUIT` command to the MySQL server, closing the current connection. Since there is no response from the MySQL, the packet that was sent is returned.

22.6.7.2.14. Method `MySQLConnection.cmd_query(statement)`

This method sends the given `statement` to the MySQL server and returns a result. If you need to send multiple statements, you have to use the `cmd_query_iter()` method.

The returned dictionary contains information depending on what kind of query was executed. If the query is a `SELECT` statement, the result contains information about columns. Other statements return a dictionary containing OK or EOF packet information.

Errors received from the MySQL server are raised as exceptions. An `InterfaceError` is raised when multiple results are found.

Returns a dictionary.

22.6.7.2.15. Method `MySQLConnection.cmd_query_iter(statement)`

Similar to the `cmd_query()` method, but returns a generator object to iterate through results. Use `cmd_query_iter()` when sending multiple statements, and separate the statements with semicolons.

The following example shows how to iterate through the results after sending multiple statements:

```
statement = 'SELECT 1; INSERT INTO t1 VALUES (); SELECT 2'
for result in cnx.cmd_query(statement, iterate=True):
    if 'columns' in result:
        columns = result['columns']
        rows = cnx.get_rows()
    else:
        # do something useful with INSERT result
```

Returns a generator object.

22.6.7.2.16. Method `MySQLConnection.cmd_refresh(options)`

This method flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument should be a bitwise value using constants from the class `constants.RefreshOption`.

See [Section 22.6.7.9, “Class `constants.RefreshOption`”](#) for a list of options.

Example:

```
>>> from mysql.connector import RefreshOption
>>> refresh = RefreshOption.LOG | RefreshOption.THREADS
>>> cnx.cmd_refresh(refresh)
```

22.6.7.2.17. Method `MySQLConnection.cmd_shutdown()`

Asks the database server to shut down. The connected user must have the `SHUTDOWN` privilege.

Returns a dictionary containing the OK packet information.

22.6.7.2.18. Method `MySQLConnection.cmd_statistics()`

Returns a dictionary containing information about the MySQL server including uptime in seconds and the number of running threads, questions, reloads, and open tables.

22.6.7.2.19. Method `MySQLConnection.disconnect()`

This method tries to send the `QUIT` command and close the socket. It does not raise any exceptions.

`MySQLConnection.close()` is a synonymous method name and more commonly used.

22.6.7.2.20. Method `MySQLConnection.get_rows(count=None)`

This method retrieves all or remaining rows of a query result set, returning a tuple containing the rows as sequence and the EOF packet information. The count argument can be used to get a given amount of rows. If count is not specified or is `None`, all rows are retrieved.

The tuple returned by `get_rows()` consists of:

- A list of tuples containing the row data as byte objects, or an empty list when no rows are available.
- EOF packet information as a dictionary containing `status_flag` and `warning_count`.

An `InterfaceError` is raised when all rows have been retrieved.

The `get_rows()` method is used by `MySQLCursor` to fetch rows.

Returns a tuple.

22.6.7.2.21. Method `MySQLConnection.get_row()`

This method retrieves the next row of a query result set, returning a tuple.

The tuple returned by `get_row()` consists of:

- The row as a tuple containing byte objects, or `None` when no more rows are available.
- EOF packet information as a dictionary containing `status_flag` and `warning_count`, or `None` when the row returned is not the last row.

The `get_row()` method is used by `MySQLCursor` to fetch rows.

22.6.7.2.22. Method `MySQLConnection.get_server_info()`

This method returns the MySQL server information verbatim, for example `'5.5.24-log'`, or `None` when not connected.

Returns a string or `None`.

22.6.7.2.23. Method `MySQLConnection.get_server_version()`

This method returns the MySQL server version as a tuple, or `None` when not connected.

Returns a tuple or `None`.

22.6.7.2.24. Method `MySQLConnection.is_connected()`

Reports whether the connection to MySQL Server is available.

This method checks whether the connection to MySQL is available using the `ping()` method, but unlike `ping()`, `is_connected()` returns `True` when the connection is available, `False` otherwise.

Returns `True` or `False`.

22.6.7.2.25. Method `MySQLConnection.isset_client_flag(flag)`

This method returns `True` if the client flag was set, `False` otherwise.

Returns `True` or `False`.

22.6.7.2.26. Method `MySQLConnection.ping(attempts=1, delay=0)`

Check whether the connection to the MySQL server is still available.

When `reconnect` is set to `True`, one or more attempts are made to try to reconnect to the MySQL server using the `reconnect()` method. Use the `delay` argument (seconds) if you want to wait between each retry.

When the connection is not available, an `InterfaceError` is raised. Use the `is_connected()` method to check the connection without raising an error.

Raises `InterfaceError` on errors.

22.6.7.2.27. Method `MySQLConnection.reconnect(attempts=1, delay=0)`

Attempt to reconnect with the MySQL server.

The argument `attempts` specifies the number of times a reconnect is tried. The `delay` argument is the number of seconds to wait between each retry.

You might set the number of attempts higher and use a longer delay when you expect the MySQL server to be down for maintenance, or when you expect the network to be temporarily unavailable.

22.6.7.2.28. Method `MySQLConnection.rollback()`

This method sends the `ROLLBACK` command to the MySQL server, undoing all data changes from the current `transaction`. Since by default, Connector/Python does not auto commit, it is possible to cancel transactions when using transactional storage engines such as `InnoDB`.

See the `commit()` method for `committing` transactions.

```
>>> cursor.execute("INSERT INTO employees (first_name) VALUES (%s)", ('Jane'))
>>> cnx.rollback()
```

22.6.7.2.29. Method `MySQLConnection.set_charset_collation(charset=None, collation=None)`

This method sets the character set and collation to be used for the current connection. The `charset` argument can be either the name of a character set, or the numerical equivalent as defined in `constants.CharacterSet`.

When `collation` is `None`, the default will be looked up and used.

The `charset` argument then be either:

In the following example, we set the character set to `latin1` and the collation will be set to the default `latin1_swedish_ci`:

```
>>> cnx = mysql.connector.connect(user='scott')
>>> cnx.set_charset('latin1')
```

Specify a specific collation as follows:

```
>>> cnx = mysql.connector.connect(user='scott')
>>> cnx.set_charset('latin1', 'latin1_general_ci')
```

22.6.7.2.30. Method `MySQLConnection.set_client_flags(flags)`

This method sets the client flags which are used when connecting with the MySQL server and returns the new value. The `flags` argument can be either an integer or a sequence of valid client flag values (see [Section 22.6.7.5, “Class constants.ClientFlag”](#)).

If `flags` is a sequence, each item in the sequence will set the flag when the value is positive or unset it when negative. For example, to unset `LONG_FLAG` and set the `FOUND_ROWS` flags:

```
>>> from mysql.connector.constants import ClientFlag
>>> cnx.set_client_flags([ClientFlag.FOUND_ROWS, -ClientFlag.LONG_FLAG])
>>> cnx.reconnect()
```

Note that client flags are only set or used when connecting with the MySQL server. It is therefore necessary to reconnect after making changes.

Returns an integer.

22.6.7.2.31. Property `MySQLConnection.autocommit`

This property is used to toggle the auto commit feature of MySQL and retrieve the current state. When the value evaluates to True, auto commit will be turned, otherwise it is turned off.

Note that auto commit is disabled by default when connecting through Connector/Python. This can be toggled using the [connection parameter `autocommit`](#).

When the auto commit is turned off, you have to [commit](#) transactions when using transactional storage engines such as InnoDB or NDBCluster.

```
>>> cnx.autocommit
False
>>> cnx.autocommit = True
>>> cnx.autocommit
True
```

Returns True or False.

22.6.7.2.32. Property `MySQLConnection.charset_name`

This property returns which character set is used for the connection whether it is connected or not.

Returns a string.

22.6.7.2.33. Property `MySQLConnection.collation_name`

This property returns which collation is used for the connection whether it is connected or not.

Returns a string.

22.6.7.2.34. Property `MySQLConnection.connection_id`

This property returns the connection ID (thread ID or session ID) for the current connection or None when not connected.

Returns a integer or None.

22.6.7.2.35. Property `MySQLConnection.database`

This property is used to set current (active) database executing the `USE` command. The property can also be used to retrieve the current database name.

```
>>> cnx.database = 'test'
>>> cnx.database = 'mysql'
>>> cnx.database
u'mysql'
```

Returns a string.

22.6.7.2.36. Property `MySQLConnection.get_warnings`

This property is used to toggle whether warnings should be fetched automatically or not. It accepts True or False (default).

Fetching warnings automatically could be useful when debugging queries. Cursors will make warnings available through the method `MySQLCursor.fetchwarnings()`.

```
>>> cnx.get_warnings = True
>>> cursor.execute('SELECT "a"+1')
>>> cursor.fetchall()
[(1.0,)]
>>> cursor.fetchwarnings()
[(u'Warning', 1292, u'Truncated incorrect DOUBLE value: 'a')]
```

Returns True or False.

22.6.7.2.37. Property `MySQLConnection.raise_on_warnings`

This property is used to toggle whether warnings should raise exceptions or not. It accepts True or False (default).

toggling `raise_on_warnings` will also toggle `get_warnings` since warnings need to be fetched so they can be raised as exceptions.

Note that you might always want to check setting SQL Mode if you would like to have the MySQL server directly report warnings as errors. It is also good to use transactional engines so transactions can be rolled back when catching the exception.

Result sets needs to be fetched completely before any exception can be raised. The following example shows the execution of a query which produces a warning

```
>>> cnx.raise_on_warnings = True
>>> cursor.execute('SELECT "a"+1')
>>> cursor.fetchall()
..
mysql.connector.errors.DataError: 1292: Truncated incorrect DOUBLE value: 'a'
```

Returns True or False.

22.6.7.2.38. Property `MySQLConnection.server_host`

This read-only property returns the hostname or IP address used for connecting with the MySQL server.

Returns a string.

22.6.7.2.39. Property `MySQLConnection.server_port`

This read-only property returns the TCP/IP port used for connecting with the MySQL server.

Returns an integer.

22.6.7.2.40. Property `MySQLConnection.sql_mode`

This property is used to retrieve and set the SQL Modes for the current. The value should be list of different modes separated by comma (","), or a sequence of modes, preferably using the constants.SQLMode class.

To unset all modes, pass an empty string or an empty sequence.

```
>>> cnx.sql_mode = 'TRADITIONAL,NO_ENGINE_SUBSTITUTION'
>>> cnx.sql_mode.split(',')
[u'STRICT_TRANS_TABLES', u'STRICT_ALL_TABLES', u'NO_ZERO_IN_DATE',
u'NO_ZERO_DATE', u'ERROR_FOR_DIVISION_BY_ZERO', u'TRADITIONAL',
u'NO_AUTO_CREATE_USER', u'NO_ENGINE_SUBSTITUTION']

>>> from mysql.connector.constants import SQLMode
>>> cnx.sql_mode = [ SQLMode.NO_ZERO_DATE, SQLMode.REAL_AS_FLOAT]
>>> cnx.sql_mode

u'REAL_AS_FLOAT,NO_ZERO_DATE'
```

Returns a string.

22.6.7.2.41. Property `MySQLConnection.time_zone`

This property is used to set the time zone session variable for the current connection and retrieve it.

```
>>> cnx.time_zone = '+00:00'
>>> cur.execute('SELECT NOW()') ; cur.fetchone()
(datetime.datetime(2012, 6, 15, 11, 24, 36),)
>>> cnx.time_zone = '-09:00'
>>> cur.execute('SELECT NOW()') ; cur.fetchone()
(datetime.datetime(2012, 6, 15, 2, 24, 44),)
>>> cnx.time_zone
u'-09:00'
```

Returns a string.

22.6.7.2.42. Property `MySQLConnection.unix_socket`

This read-only property returns the UNIX socket user for connecting with the MySQL server.

Returns a string.

22.6.7.2.43. Property `MySQLConnection.user`

This read-only property returns the username used for connecting with the MySQL server.

Returns a string.

22.6.7.3. Class `cursor.MySQLCursor`

The `MySQLCursor` class is used to instantiate object which can execute operation such as SQL queries. They interact with the MySQL server using a `MySQLConnection` object.

22.6.7.3.1. Constructor `cursor.MySQLCursor`

The constructor initializes the instance with the optional `connection`, which should be an instance of `MySQLConnection`.

In most cases, the `MySQLConnection` method `cursor()` is used to instantiate a `MySQLCursor` object.

22.6.7.3.2. Method `MySQLCursor.callproc(procname, args=())`

This method calls a stored procedure with the given name. The `args` sequence of parameters must contain one entry for each argument that the routine expects. The result is returned as modified copy of the input sequence. Input parameters are left untouched, output and input/output parameters replaced with possibly new values.

Result set provided by the stored procedure are automatically fetched and stored as `MySQLBufferedCursor` instances. See `stored_results()` for more information.

The following example shows how to execute a stored procedure which takes two parameters, multiplies the values and returns the product:

```
# Definition of the multiply stored procedure:
# CREATE PROCEDURE multiply(IN pFac1 INT, IN pFac2 INT, OUT pProd INT)
# BEGIN
#   SET pProd := pFac1 * pFac2;
# END

>>> args = (5, 5, 0) # 0 is to hold value of the OUT parameter pProd
>>> cursor.callproc('multiply', args)
('5', '5', 25L)
```

22.6.7.3.3. Method `MySQLCursor.close()`

This method will close the MySQL cursor, resetting all results and removing the connection.

Use `close()` every time you are done using the cursor.

22.6.7.3.4. Method `MySQLCursor.execute(operation, params=None, multi=False)`

This method prepare the given database `operation` (query or command). The parameters found in the tuple or dictionary `params` will be bound to the variables in the operation. Variables are specified using `%s` markers or named markers `%(name)s`.

For example, insert information about a new employee and selecting again the data of this person:

```
insert = (
"INSERT INTO employees (emp_no, first_name, last_name, hire_date) "
"VALUES (%s, %s, %s, %s)"
data = (2, 'Jane', 'Doe', datetime.date(2012, 3, 23))
cursor.execute(insert, data)

select = "SELECT * FROM employees WHERE emp_no = %(emp_no)s"
cursor.execute(select, { 'emp_no': 2 })
```

Note that the data is converted from Python object to something MySQL understand. In the above example, the `datetime.date()` instance is converted to `'2012-03-23'` in the above example.

When `multi` is set to `True`, `execute()` will be able to execute multiple statements. It will return an iterator which makes it possible to go through all results for each statement. Note that using parameters is not working well in this case, and it's usually a good idea to execute each statement on its own.

In the following example we select and insert data in one operation and display the result:

```
operation = 'SELECT 1; INSERT INTO t1 VALUES (); SELECT 2'
for result in cursor.execute(operation):
    if result.with_rows:
        print("Statement '{}' has following rows:".format(
            result.statement))
        print(result.fetchall())
    else:
        print("Affected row(s) by query '{}' was {}".format(
            result.statement, result.rowcount))
```

If the connection was configured to fetch warnings, warnings generated by the operation will be available through the method `MySQLCursor.fetchwarnings()`.

Returns an iterator when `multi` is `True`.

22.6.7.3.5. Method `MySQLCursor.executemany(operation, seq_params)`

This method prepares a database operation (query or command) and then execute it against all parameter sequences or mappings found in the sequence `seq_of_params`.

The `executemany()` is simply iterating through the sequence of parameters calling the `execute()` method. Inserting data, however, is optimized by batching them using the multiple rows syntax.

In the following example we are inserting 3 records:

```
data = [
    ('Jane', date(2005, 2, 12)),
    ('Joe', date(2006, 5, 23)),
    ('John', date(2010, 10, 3)),
]
stmt = "INSERT INTO employees (first_name, hire_date) VALUES (%s, %s)"
cursor.executemany(stmt, data)
```

In the above example, the INSERT statement sent to MySQL would be as follows: `INSERT INTO employees (first_name, hire_date) VALUES ('Jane', '2005-02-12'), ('Joe', '2006-05-23'), ('John', '2010-10-03')`.

Note that it is not possible to execute multiple statements using the `executemany()` method. Doing so will raise an `InternalError` exception.

22.6.7.3.6. Method `MySQLCursor.fetchall()`

The method fetches all or remaining rows of a query result set, returning a list of tuples. An empty list is returned when no rows are (anymore) available.

The following examples shows how to retrieve the first 2 rows of a result set, and then retrieve the remaining rows:

```
>>> cursor.execute("SELECT * FROM employees ORDER BY emp_no")
>>> head_rows = cursor.fetchmany(size=2)
>>> remaining_rows = cursor.fetchall()
```

Note that you have to fetch all rows before being able to execute new queries using the same connection.

Returns a list of tuples or empty list when no rows available.

22.6.7.3.7. Method `MySQLCursor.fetchmany(size=1)`

This method fetches the next set of rows of a query results, returning a list of tuples. An empty list is returned when no more rows are available.

The number of rows returned can be specified using the `size` argument, which defaults to one. Fewer rows might be returned, when there are not more rows available than specified by the argument.

Note that you have to fetch all rows before being able to execute new queries using the same connection.

Returns a list of tuples or empty list when no rows available.

22.6.7.3.8. Method `MySQLCursor.fetchone()`

This method retrieves the next row of a query result set, returning a single sequence, or `None` when no more data is available. The returned tuple consists of data returned by the MySQL server converted to Python objects.

The `fetchone()` method is used by `fetchmany()` and `fetchall()`. It is also used when using the `MySQLCursor` instance as an iterator.

The following examples show how to iterate through the result of a query using `fetchone()`:

```
# Using a while-loop
cursor.execute("SELECT * FROM employees")
row = cursor.fetchone()
while row is not None:
    print(row)
    row = cursor.fetchone()

# Using the cursor as iterator
cursor.execute("SELECT * FROM employees")
for row in cursor:
    print(row)
```

Note that you have to fetch all rows before being able to execute new queries using the same connection.

Returns a tuple or `None`.

22.6.7.3.9. Method `MySQLCursor.fetchwarnings()`

This method returns a list of tuples containing warnings generated by previously executed statement. Use the connection's `get_warnings` property to toggle whether warnings has to be fetched.

The following example shows a `SELECT` statement which generated a warning:

```
>>> cnx.get_warnings = True
>>> cursor.execute('SELECT "a"+1')
>>> cursor.fetchall()
[(1.0,)]
>>> cursor.fetchwarnings()
[(u'Warning', 1292, u'Truncated incorrect DOUBLE value: 'a')]
```

It is also possible to raise errors when warnings are found. See the `MySQLConnection` property `raise_on_warnings`.

Returns a list of tuples.

22.6.7.3.10. Method `MySQLCursor.stored_results()`

This method returns an list iterator object which can be used to go through result sets provided by stored procedures after calling them using the `callproc()` method.

In the following example we execute a stored procedure which will provide two result sets. We use `stored_results()` to retrieve them:

```
>>> cursor.callproc('sp1')
()
>>> for result in cursor.stored_results():
...     print result.fetchall()
...
[(1,)]
[(2,)]
```

Note that the result sets stay available until you executed another operation or call another stored procedure.

Returns a listiterator.

22.6.7.3.11. Property `MySQLCursor.column_names`

This read-only property returns the column names of a result set as sequence of (unicode) strings.

The following example shows how you can create a dictionary out of a tuple containing data with keys using `column_names`:

```
cursor.execute("SELECT last_name, first_name, hire_date "
              "FROM employees WHERE emp_no = %s", (123,))
row = dict(zip(cursor.column_names, cursor.fetchone()))
print("{last_name}, {first_name}: {hire_date}".format(row))
```

Returns a tuple.

22.6.7.3.12. Property `MySQLCursor.statement`

This read-only property returns the last executed statement. In case multiple statements were executed, it will show the actual statement.

The `statement` property might be useful for debugging and showing what was send to the MySQL server.

Returns a string.

22.6.7.3.13. Property `MySQLCursor.with_rows`

This read-only property will return True when the result of the executed operation provides rows.

The `with_rows` property is useful when executing multiple statements and you need to fetch rows. In the following example we only report the affected rows by the `UPDATE` statement:

```
import mysql.connector
cnx = mysql.connector.connect(user='scott', database='test')
cursor = cnx.cursor()
operation = 'SELECT 1; UPDATE t1 SET c1 = 2; SELECT 2'
for result in cursor.execute(operation, multi=True):
    if result.with_rows:
        result.fetchall()
    else:
        print("Updated row(s): {}".format(result.rowcount))
```

22.6.7.4. Class `cursor.MySQLCursorBuffered`

This class is inheriting from `cursor.MySQLCursor` and if needed automatically retrieves rows after an operation has been executed.

`MySQLCursorBuffered` can be useful in situations where two queries, with small result sets, need to be combined or computed with each other.

You can either use the `buffered` argument when using the connection's `cursor()` method, or you can use the [buffered connection option](#) to make all created cursors by default buffering.

```
import mysql.connector

cnx = mysql.connector.connect()

# Only this particular cursor will be buffering results
cursor.cursor(buffered=True)

# All cursors by default buffering
cnx = mysql.connector.connect(buffered=True)
```

See [Section 22.6.5.1, "Tutorial: Raise employee's salary using a buffering cursor"](#) for a practical use case.

22.6.7.5. Class `constants.ClientFlag`

This class provides constants defining MySQL client flags which can be used upon connection to configure the session. The `ClientFlag` class is available when importing `mysql.connector`.

```
>>> import mysql.connector
>>> mysql.connector.constants.ClientFlag.FOUND_ROWS
2
```

See [Section 22.6.7.2.30, "Method `MySQLConnection.set_client_flags\(flags\)`"](#) and the [connection argument `client_flag`](#).

Note that the `ClientFlag` class can not be instantiated.

22.6.7.6. Class `constants.FieldType`

This class provides all supported MySQL field or data types. They can be useful when dealing with raw data or defining your own converters. The field type is stored with every cursor in the description for each column.

The following example shows how you can print the name of the data types for each of the columns in the result set.

```
from __future__ import print_function
import mysql.connector
from mysql.connector import FieldType

cnx = mysql.connector.connect(user='scott', database='test')
cursor = cnx.cursor()

cursor.execute(
    "SELECT DATE(NOW()) AS `c1`, TIME(NOW()) AS `c2`, "
    "NOW() AS `c3`, 'a string' AS `c4`, 42 AS `c5`")
rows = cursor.fetchall()

for desc in cursor.description:
    colname = desc[0]
    coltype = desc[1]
```

```
print("Column {} has type {}".format(
    colname, FieldType.get_info(coltype)))

cursor.close()
cnx.close()
```

Note that the `FieldType` class can not be instantiated.

22.6.7.7. Class `constants.SQLMode`

This class provides all known MySQL [Server SQL Modes](#). It is mostly used when setting the SQL modes at connection time using the connection's property `sql_mode`. See [Section 22.6.7.2.40](#), “[Property `MySQLConnection.sql_mode`](#)”.

Note that the `SQLMode` class can not be instantiated.

22.6.7.8. Class `constants.CharacterSet`

This class provides all known MySQL characters sets and their default collations. See [Section 22.6.7.2.29](#), “[Method `MySQLConnection.set_charset_collation\(charset=None, collation=None\)`](#)” for examples.

Note that the `CharacterSet` class can not be instantiated.

22.6.7.9. Class `constants.RefreshOption`

- `RefreshOption.GRANT`

Refresh the grant tables, like `FLUSH PRIVILEGES`.

- `RefreshOption.LOG`

Flush the logs, like `FLUSH LOGS`.

- `RefreshOption.TABLES`

Flush the table cache, like `FLUSH TABLES`.

- `RefreshOption.HOSTS`

Flush the host cache, like `FLUSH HOSTS`.

- `RefreshOption.STATUS`

Reset status variables, like `FLUSH STATUS`.

- `RefreshOption.THREADS`

Flush the thread cache.

- `RefreshOption.SLAVE`

On a slave replication server, reset the master server information and restart the slave, like [RESET SLAVE](#).

- `RefreshOption.MASTER`

On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like [RESET MASTER](#).

22.6.8. Connector/Python FAQ

Frequently asked questions.

22.7. libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions.

| Function | When to Call |
|-----------------------------------|---|
| <code>mysql_library_init()</code> | Should be called before any other MySQL function is called, preferably early in the <code>main()</code> function. |
| <code>mysql_library_end()</code> | Should be called before your program exits. |
| <code>mysql_thread_init()</code> | Should be called in each thread you create that accesses MySQL. |
| <code>mysql_thread_end()</code> | Should be called before calling <code>pthread_exit()</code> |

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, be sure to compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 4.1 headers, do not compile your application against MySQL 5.1 headers, or vice versa.

The `mysql_library_xxx()` functions are also included in `libmysqlclient.a` to enable you to change between the embedded and the client/server version by just linking your application with the right library. See [Section 22.8.3.40](#), “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, define the `HAVE_EMBEDDED_PRIVILEGE_CONTROL` [156] compiler flag when you invoke `CMake` to configure your MySQL distribution. See [Section 2.10.4](#), “MySQL Source-Configuration Options”.

22.7.1. Compiling Programs with `libmysqld`

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `-DWITH_EMBEDDED_SERVER=1` [155] option. See [Section 2.10.4](#), “MySQL Source-Configuration Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```
gcc mysql_test.c -o mysql_test -lz \  
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

22.7.2. Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- `InnoDB` is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the `event_scheduler` [498] system variable is disabled.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

22.7.3. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` [248] option as one of the elements of the second argument of the `mysql_library_init()` function. See Section 22.8.3.40, “`mysql_library_init()`”, for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See [Section 4.2.3.3, "Using Option Files"](#).

22.7.4. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

Example 1

`test1_libmysqld.c`

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
    { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",
    "libmysqld_client", NULL };

int main(void)
{
    mysql_library_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
    mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

    mysql_real_connect(mysql, NULL, NULL, NULL, "database1", 0, NULL, 0);

    mysql_query(mysql, "SELECT column1, column2 FROM table1");

    results = mysql_store_result(mysql);

    while((record = mysql_fetch_row(results))) {
        printf("%s - %s\n", record[0], record[1]);
    }

    mysql_free_result(results);
    mysql_close(mysql);
    mysql_library_end();

    return 0;
}
```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld -lz \
    `/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Example 2

To try the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

`test2_libmysqld.c`

```

/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
    "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
    MYSQL *one, *two;

    /* mysql_library_init() must be called before any other mysql
     * functions.
     *
     * You can use mysql_library_init(0, NULL, NULL), and it
     * initializes the server using groups = {
     *   "server", "embedded", NULL
     * }.
     *
     * In your $HOME/.my.cnf file, you probably want to put:
     *
     * [test2_libmysqld_SERVER]
     * language = /path/to/source/of/mysql/sql/share/english
     *
     * You could, of course, modify argc and argv before passing
     * them to this function. Or you could create new ones in any
     * way you like. But all of the arguments in argv (except for
     * argv[0], which is the program name) should be valid options
     * for the MySQL server.
     *
     * If you link this client against the normal mysqlclient
     * library, this function is just a stub that does nothing.
     */
    mysql_library_init(argc, argv, (char **)server_groups);

    one = db_connect("test");
    two = db_connect(NULL);

    db_do_query(one, "SHOW TABLE STATUS");
    db_do_query(two, "SHOW DATABASES");

    mysql_close(two);
    mysql_close(one);

    /* This must be called after all other mysql functions */
    mysql_library_end();

```

```

    exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
     * Notice that the client and server use separate group names.
     * This is critical, because the server does not accept the
     * client's options, and vice versa.
     */
    mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
    if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
        die(db, "mysql_real_connect failed: %s", mysql_error(db));

    return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;

    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES *res;
        MYSQL_ROW row, end_row;
        int num_fields;

        if (!(res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
        {
            (void)fputs(">> ", stdout);
            for (end_row = row + num_fields; row < end_row; ++row)
                (void)printf("%s\t", row ? (char*)*row : "NULL");
            (void)putc('\n', stdout);
        }
        (void)putc('\n', stdout);
        mysql_free_result(res);
    }
    else
        (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));
}

```

```

    return;

err:
    die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}

```

GNUmakefile

```

22.8. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and enables C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `client` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/Net) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See [Chapter 4, MySQL Programs](#), for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` [519] parameter when the server is started. See [Section 8.11.2, "Tuning Server Parameters"](#).

The MySQL server shrinks each communication buffer to `net_buffer_length` [531] bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see [Section 22.8.17.2, "How to Write a Threaded Client"](#). For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see [Section 22.7, "libmysql, the Embedded MySQL Server Library"](#).

**Note**

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

22.8.1. C API Data Structures

This section describes C API data structures other than those used for prepared statements. For information about the latter, see [Section 22.8.5, "C API Prepared Statement Data Structures"](#).

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. Do not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains metadata: information about a field, such as the field's name, type, and size. Its members are described in more detail later in this section. You may obtain the `MYSQL_FIELD` structures

for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
        (unsigned long) mysql_num_rows(result));
```

- `my_bool`

A boolean type, for values that are true (nonzero) or false (zero).

The `MYSQL_FIELD` structure contains the members described in the following list. The definitions apply primarily for columns of result sets such as those produced by `SELECT` statements. As of MySQL 5.5.3, `MYSQL_FIELD` structures are also used to provide metadata for `OUT` and `INOUT` parameters returned from stored procedures executed using prepared `CALL` statements. For such parameters, some of the structure members have a meaning different from the meaning for column values.

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias. For a procedure parameter, the parameter name.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored. For a procedure parameter, the parameter name.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string. For a procedure parameter, the procedure name.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the underlying table. For a `UNION`, the value is the empty string. For a procedure parameter, the procedure name.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a `UNION`, the value is the empty string. For a procedure parameter, the name of the database containing the procedure.

- `char * catalog`

The catalog name. This value is always "def".

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field. This corresponds to the display length, in bytes.

The server determines the `length` value before it generates the result set, so this is the minimum length required for a data type capable of holding the largest possible value from the result column, without knowing in advance the actual values that will be produced by the query for the result set.

- `unsigned long max_length`

The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the "widest" value is `-12.345`, `max_length` is 7 (the length of `'-12.345'`).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See [Section 22.8.5, "C API Prepared Statement Data Structures"](#).) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See [Section 22.8.7.3, "mysql_stmt_attr_set\(\)"](#), and [Section 22.8.7.28, "mysql_stmt_store_result\(\)"](#).)

- `unsigned int name_length`

The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

The length of `table`.

- `unsigned int org_table_length`

The length of `org_table`.

- `unsigned int db_length`

The length of `db`.

- `unsigned int catalog_length`

The length of `catalog`.

- `unsigned int def_length`

The length of `def`.

- `unsigned int flags`

Bit-flags that describe the field. The `flags` value may have zero or more of the bits set that are shown in the following table.

| Flag Value | Flag Description |
|------------------------------------|--|
| <code>NOT_NULL_FLAG</code> | Field can't be <code>NULL</code> |
| <code>PRI_KEY_FLAG</code> | Field is part of a primary key |
| <code>UNIQUE_KEY_FLAG</code> | Field is part of a unique key |
| <code>MULTIPLE_KEY_FLAG</code> | Field is part of a nonunique key |
| <code>UNSIGNED_FLAG</code> | Field has the <code>UNSIGNED</code> attribute |
| <code>ZEROFILL_FLAG</code> | Field has the <code>ZEROFILL</code> attribute |
| <code>BINARY_FLAG</code> | Field has the <code>BINARY</code> attribute |
| <code>AUTO_INCREMENT_FLAG</code> | Field has the <code>AUTO_INCREMENT</code> attribute |
| <code>ENUM_FLAG</code> | Field is an <code>ENUM</code> (deprecated) |
| <code>SET_FLAG</code> | Field is a <code>SET</code> (deprecated) |
| <code>BLOB_FLAG</code> | Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated) |
| <code>TIMESTAMP_FLAG</code> | Field is a <code>TIMESTAMP</code> (deprecated) |
| <code>NUM_FLAG</code> | Field is numeric; see additional notes following table |
| <code>NO_DEFAULT_VALUE_FLAG</code> | Field has no default value; see additional notes following table |

Some of these flags indicate data type information and are superseded by or used in conjunction with the `MYSQL_TYPE_XXX` value in the `field->type` member described later:

- To check for `BLOB` or `TIMESTAMP` values, check whether `type` is `MYSQL_TYPE_BLOB` or `MYSQL_TYPE_TIMESTAMP`. (The `BLOB_FLAG` and `TIMESTAMP_FLAG` flags are unneeded.)
- `ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

`NUM_FLAG` indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_NEWDECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

`NO_DEFAULT_VALUE_FLAG` indicates that a column has no `DEFAULT` clause in its definition. This does not apply to `NULL` columns (because such columns have a default of `NULL`), or to `AUTO_INCREMENT` columns (which have an implied default value).

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

You may use the convenience macros shown in the following table to determine the boolean status of the `flags` value.

| Flag Status | Description |
|---------------------------------|---|
| <code>IS_NOT_NULL(flags)</code> | True if this field is defined as <code>NOT NULL</code> |
| <code>IS_PRI_KEY(flags)</code> | True if this field is a primary key |
| <code>IS_BLOB(flags)</code> | True if this field is a <code>BLOB</code> or <code>TEXT</code> (deprecated; test <code>field->type</code> instead) |

- `unsigned int decimals`

The number of decimals for numeric fields.

- `unsigned int charsetnr`

An ID number that indicates the character set/collation pair for the field.

To distinguish between binary and nonbinary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

`charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| binary   | binary  | 63 | Yes     | Yes      | 1       |
+-----+-----+-----+-----+-----+-----+

mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
-> FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
+-----+-----+
| COLLATION_NAME | CHARACTER_SET_NAME |
+-----+-----+
| utf8_general_ci | utf8                |
+-----+-----+
```

- `enum enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

| Type Value | Type Description |
|------------------------------------|---|
| <code>MYSQL_TYPE_TINY</code> | <code>TINYINT</code> field |
| <code>MYSQL_TYPE_SHORT</code> | <code>SMALLINT</code> field |
| <code>MYSQL_TYPE_LONG</code> | <code>INTEGER</code> field |
| <code>MYSQL_TYPE_INT24</code> | <code>MEDIUMINT</code> field |
| <code>MYSQL_TYPE_LONGLONG</code> | <code>BIGINT</code> field |
| <code>MYSQL_TYPE_DECIMAL</code> | <code>DECIMAL</code> or <code>NUMERIC</code> field |
| <code>MYSQL_TYPE_NEWDECIMAL</code> | Precision math <code>DECIMAL</code> or <code>NUMERIC</code> |
| <code>MYSQL_TYPE_FLOAT</code> | <code>FLOAT</code> field |

| Type Value | Type Description |
|------------------------------------|--|
| <code>MYSQL_TYPE_DOUBLE</code> | <code>DOUBLE</code> or <code>REAL</code> field |
| <code>MYSQL_TYPE_BIT</code> | <code>BIT</code> field |
| <code>MYSQL_TYPE_TIMESTAMP</code> | <code>TIMESTAMP</code> field |
| <code>MYSQL_TYPE_DATE</code> | <code>DATE</code> field |
| <code>MYSQL_TYPE_TIME</code> | <code>TIME</code> field |
| <code>MYSQL_TYPE_DATETIME</code> | <code>DATETIME</code> field |
| <code>MYSQL_TYPE_YEAR</code> | <code>YEAR</code> field |
| <code>MYSQL_TYPE_STRING</code> | <code>CHAR</code> or <code>BINARY</code> field |
| <code>MYSQL_TYPE_VAR_STRING</code> | <code>VARCHAR</code> or <code>VARBINARY</code> field |
| <code>MYSQL_TYPE_BLOB</code> | <code>BLOB</code> or <code>TEXT</code> field (use <code>max_length</code> to determine the maximum length) |
| <code>MYSQL_TYPE_SET</code> | <code>SET</code> field |
| <code>MYSQL_TYPE_ENUM</code> | <code>ENUM</code> field |
| <code>MYSQL_TYPE_GEOMETRY</code> | Spatial field |
| <code>MYSQL_TYPE_NULL</code> | <code>NULL</code> -type field |

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to `TRUE` if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

`ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

22.8.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 22.8.3, “C API Function Descriptions”](#).

Table 22.31. C API Function Names and Descriptions

| Function | Description |
|---|--|
| <code>my_init()</code> | Initialize global variables, and thread handler in thread-safe programs |
| <code>mysql_affected_rows()</code> | Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query |
| <code>mysql_autocommit()</code> | Toggles autocommit mode on/off |
| <code>mysql_change_user()</code> | Changes user and database on an open connection |
| <code>mysql_character_set_name()</code> | Return default character set name for current connection |
| <code>mysql_client_find_plugin()</code> | Return pointer to plugin |
| <code>mysql_client_register_plugin()</code> | Register a plugin |
| <code>mysql_close()</code> | Closes a server connection |
| <code>mysql_commit()</code> | Commits the transaction |
| <code>mysql_connect()</code> | Connects to a MySQL server (this function is deprecated; use <code>mysql_real_connect()</code> instead) |

| Function | Description |
|---|---|
| <code>mysql_create_db()</code> | Creates a database (this function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead) |
| <code>mysql_data_seek()</code> | Seeks to an arbitrary row number in a query result set |
| <code>mysql_debug()</code> | Does a <code>DEBUG_PUSH</code> with the given string |
| <code>mysql_drop_db()</code> | Drops a database (this function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead) |
| <code>mysql_dump_debug_info()</code> | Makes the server write debug information to the log |
| <code>mysql_eof()</code> | Determines whether the last row of a result set has been read (this function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead) |
| <code>mysql_errno()</code> | Returns the error number for the most recently invoked MySQL function |
| <code>mysql_error()</code> | Returns the error message for the most recently invoked MySQL function |
| <code>mysql_escape_string()</code> | Escapes special characters in a string for use in an SQL statement |
| <code>mysql_fetch_field()</code> | Returns the type of the next table field |
| <code>mysql_fetch_field_direct()</code> | Returns the type of a table field, given a field number |
| <code>mysql_fetch_fields()</code> | Returns an array of all field structures |
| <code>mysql_fetch_lengths()</code> | Returns the lengths of all columns in the current row |
| <code>mysql_fetch_row()</code> | Fetches the next row from the result set |
| <code>mysql_field_count()</code> | Returns the number of result columns for the most recent statement |
| <code>mysql_field_seek()</code> | Puts the column cursor on a specified column |
| <code>mysql_field_tell()</code> | Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code> |
| <code>mysql_free_result()</code> | Frees memory used by a result set |
| <code>mysql_get_character_set_info()</code> | Return information about default character set |
| <code>mysql_get_client_info()</code> | Returns client version information as a string |
| <code>mysql_get_client_version()</code> | Returns client version information as an integer |
| <code>mysql_get_host_info()</code> | Returns a string describing the connection |
| <code>mysql_get_proto_info()</code> | Returns the protocol version used by the connection |
| <code>mysql_get_server_info()</code> | Returns the server version number |
| <code>mysql_get_server_version()</code> | Returns version number of server as an integer |
| <code>mysql_get_ssl_cipher()</code> | Return current SSL cipher |
| <code>mysql_hex_string()</code> | Encode string in hexadecimal format |
| <code>mysql_info()</code> | Returns information about the most recently executed query |
| <code>mysql_init()</code> | Gets or initializes a <code>MYSQL</code> structure |
| <code>mysql_insert_id()</code> | Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query |
| <code>mysql_kill()</code> | Kills a given thread |
| <code>mysql_library_end()</code> | Finalize the MySQL C API library |
| <code>mysql_library_init()</code> | Initialize the MySQL C API library |

| Function | Description |
|--|---|
| <code>mysql_list_dbs()</code> | Returns database names matching a simple regular expression |
| <code>mysql_list_fields()</code> | Returns field names matching a simple regular expression |
| <code>mysql_list_processes()</code> | Returns a list of the current server threads |
| <code>mysql_list_tables()</code> | Returns table names matching a simple regular expression |
| <code>mysql_load_plugin()</code> | Load a plugin |
| <code>mysql_load_plugin_v()</code> | Load a plugin |
| <code>mysql_more_results()</code> | Checks whether any more results exist |
| <code>mysql_next_result()</code> | Returns/initiates the next result in multiple-result executions |
| <code>mysql_num_fields()</code> | Returns the number of columns in a result set |
| <code>mysql_num_rows()</code> | Returns the number of rows in a result set |
| <code>mysql_options()</code> | Sets connect options for <code>mysql_real_connect()</code> |
| <code>mysql_ping()</code> | Checks whether the connection to the server is working, reconnecting as necessary |
| <code>mysql_plugin_options()</code> | Set a plugin option |
| <code>mysql_query()</code> | Executes an SQL query specified as a null-terminated string |
| <code>mysql_real_connect()</code> | Connects to a MySQL server |
| <code>mysql_real_escape_string()</code> | Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection |
| <code>mysql_real_query()</code> | Executes an SQL query specified as a counted string |
| <code>mysql_refresh()</code> | Flush or reset tables and caches |
| <code>mysql_reload()</code> | Tells the server to reload the grant tables |
| <code>mysql_rollback()</code> | Rolls back the transaction |
| <code>mysql_row_seek()</code> | Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code> |
| <code>mysql_row_tell()</code> | Returns the row cursor position |
| <code>mysql_select_db()</code> | Selects a database |
| <code>mysql_server_end()</code> | Finalize the MySQL C API library |
| <code>mysql_server_init()</code> | Initialize the MySQL C API library |
| <code>mysql_set_character_set()</code> | Set default character set for current connection |
| <code>mysql_set_local_infile_defaults()</code> | Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values |
| <code>mysql_set_local_infile_handler()</code> | Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks |
| <code>mysql_set_server_option()</code> | Sets an option for the connection (like <code>multi-statements</code>) |
| <code>mysql_sqlstate()</code> | Returns the SQLSTATE error code for the last error |
| <code>mysql_shutdown()</code> | Shuts down the database server |
| <code>mysql_ssl_set()</code> | Prepare to establish SSL connection to server |
| <code>mysql_stat()</code> | Returns the server status as a string |
| <code>mysql_store_result()</code> | Retrieves a complete result set to the client |

| Function | Description |
|------------------------------------|--|
| <code>mysql_thread_end()</code> | Finalize thread handler |
| <code>mysql_thread_id()</code> | Returns the current thread ID |
| <code>mysql_thread_init()</code> | Initialize thread handler |
| <code>mysql_thread_safe()</code> | Returns 1 if the clients are compiled as thread-safe |
| <code>mysql_use_result()</code> | Initiates a row-by-row result set retrieval |
| <code>mysql_warning_count()</code> | Returns the warning count for the previous SQL statement |

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `mysqlclient` C client library and the `mysqld` embedded server library, so it is used whether you build a regular client program by linking with the `-libmysqlclient` flag, or an embedded server application by linking with the `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user name, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. Treat these statements the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Choose the approach that is most appropriate for each client application. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you *must* retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is nonzero, the statement should have returned rows, but didn't. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` enable you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the

most recently invoked function that can succeed or fail, enabling you to determine when an error occurred and what it was.

22.8.3. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                /* correct */
    ... error ...

if (result < 0)           /* incorrect */
    ... error ...

if (result == -1)        /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

22.8.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

Description

`mysql_affected_rows()` may be called immediately after executing a statement with `mysql_query()` or `mysql_real_query()`. It returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value is 1 if the row is inserted as a new row and 2 if an existing row is updated.

Following a `CALL` statement for a stored procedure, `mysql_affected_rows()` returns the value that it would return for the last statement executed within the procedure, or 0 if that statement would return -1. Within the procedure, you can use `ROW_COUNT()` [1196] at the SQL level to obtain the affected-rows value for individual statements.

As of MySQL 5.5.5, `mysql_affected_rows()` returns a meaningful value for a wider range of statements. For details, see the description for `ROW_COUNT()` [1196] in Section 12.14, “Information Functions”.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`.

Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

Errors

None.

Example

```
char *stmt = "UPDATE products SET cost=cost*1.25
             WHERE group=10";
mysql_query(&mysql,stmt);
printf("%ld products updated",
       (long) mysql_affected_rows(&mysql));
```

22.8.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

Return Values

Zero if successful. Nonzero if an error occurred.

Errors

None.

22.8.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password,
                          const char *db)
```

Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case, the user and database are not changed.

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command resets the state as if one had done a new connect. (See [Section 22.8.12, "Controlling Automatic Reconnection Behavior"](#).) It always performs a `ROLLBACK` of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values

of the corresponding global system variables. Prepared statements are released and `HANDLER` variables are closed. Locks acquired with `GET_LOCK()` [1199] are released. These effects occur even if the user didn't change.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC` [4030]

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR` [4030]

The MySQL server has gone away.

- `CR_SERVER_LOST` [4030]

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR` [4029]

An unknown error occurred.

- `ER_UNKNOWN_COM_ERROR` [3982]

The MySQL server doesn't implement this command (probably an old server).

- `ER_ACCESS_DENIED_ERROR` [3982]

The user or password was wrong.

- `ER_BAD_DB_ERROR` [3982]

The database didn't exist.

- `ER_DBACCESS_DENIED_ERROR` [3982]

The user did not have access rights to the database.

- `ER_WRONG_DB_NAME` [3986]

The database name was too long.

Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

22.8.3.4. `mysql_character_set_name()`

```
const char *mysql_character_set_name(MYSQL *mysql)
```

Description

Returns the default character set name for the current connection.

Return Values

The default character set name

Errors

None.

22.8.3.5. `mysql_close()`

```
void mysql_close(MYSQL *mysql)
```

Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

Return Values

None.

Errors

None.

22.8.3.6. `mysql_commit()`

```
my_bool mysql_commit(MYSQL *mysql)
```

Description

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` [489] system variable. In particular, if the value of `completion_type` [489] is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

Return Values

Zero if successful. Nonzero if an error occurred.

Errors

None.

22.8.3.7. `mysql_connect()`

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

Description

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

Return Values

Same as for `mysql_real_connect()`.

Errors

Same as for `mysql_real_connect()`.

22.8.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

Return Values

Zero if the database was created successfully. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR` [4030]
The MySQL server has gone away.
- `CR_SERVER_LOST` [4030]
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR` [4029]
An unknown error occurred.

Example

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

```
}
```

22.8.3.9. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number. Specify a value in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

None.

Errors

None.

22.8.3.10. `mysql_debug()`

```
void mysql_debug(const char *debug)
```

Description

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See [MySQL Internals: Porting to Other Systems](#).

Return Values

None.

Errors

None.

Example

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:0,/tmp/client.trace");
```

22.8.3.11. `mysql_drop_db()`

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

Description

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

Return Values

Zero if the database was dropped successfully. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

Example

```
if(mysql_drop_db(&mysql, "my_database"))  
    fprintf(stderr, "Failed to drop the database: Error: %s\n",  
            mysql_error(&mysql));
```

22.8.3.12. `mysql_dump_debug_info()`

```
int mysql_dump_debug_info(MYSQL *mysql)
```

Description

Instructs the server to write some debug information to the log. For this to work, the connected user must have the [SUPER \[697\]](#) privilege.

Return Values

Zero if the command was successful. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

22.8.3.13. `mysql_eof()`

```
my_bool mysql_eof(MYSQL_RES *result)
```

Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a `NULL` return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero if no error occurred. Nonzero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
```

```
fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

22.8.3.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix C, Errors, Error Codes, and Common Problems](#).

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

Errors

None.

22.8.3.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, the following two tests are equivalent:

```
if(*mysql_error(&mysql))
{
    // an error occurred
}

if(mysql_error(&mysql)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See [Section 10.2, “Setting the Error Message Language”](#).

Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

Errors

None.

22.8.3.16. `mysql_escape_string()`

Use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

22.8.3.17. `mysql_fetch_field()`

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

Errors

None.

Example

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

}

22.8.3.18. `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int fieldnr)
```

Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. Use this function to retrieve the definition for an arbitrary column. Specify a value for `fieldnr` in the range from 0 to `mysql_num_fields(result)-1`.

Return Values

The `MYSQL_FIELD` structure for the specified column.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

22.8.3.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
```

```
printf("Field %u is %s\n", i, fields[i].name);
}
```

22.8.3.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). `NULL` if an error occurred.

Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns `NULL` if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n",
              i, lengths[i]);
    }
}
```

22.8.3.21. `mysql_fetch_row()`

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. `NULL` values in the row are indicated by `NULL` pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

Errors

Note that error is not reset between calls to `mysql_fetch_row()`

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
    unsigned long *lengths;
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("[%.*s] ", (int) lengths[i],
                row[i] ? row[i] : "NULL");
    }
    printf("\n");
}
```

22.8.3.22. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 22.8.11.1, “Why `mysql_store_result\(\)` Sometimes Returns `NULL` After `mysql_query\(\)` Returns Success”](#).

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```

MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}

```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

22.8.3.23. `mysql_field_seek()`

```

MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET
offset)

```

Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

Return Values

The previous value of the field cursor.

Errors

None.

22.8.3.24. `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

Return Values

The current offset of the field cursor.

Errors

None.

22.8.3.25. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

Return Values

None.

Errors

None.

22.8.3.26. `mysql_get_character_set_info()`

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

Description

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

Example

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set+collation number: %d\n", cs.number);
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

```
}
```

22.8.3.27. `mysql_get_client_info()`

```
const char *mysql_get_client_info(void)
```

Description

Returns a string that represents the client library version.

Return Values

A character string that represents the MySQL client library version.

Errors

None.

22.8.3.28. `mysql_get_client_version()`

```
unsigned long mysql_get_client_version(void)
```

Description

Returns an integer that represents the client library version. The value has the format `XYZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

Return Values

An integer that represents the MySQL client library version.

Errors

None.

22.8.3.29. `mysql_get_host_info()`

```
const char *mysql_get_host_info(MYSQL *mysql)
```

Description

Returns a string describing the type of connection in use, including the server host name.

Return Values

A character string representing the server host name and the connection type.

Errors

None.

22.8.3.30. `mysql_get_proto_info()`

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

Description

Returns the protocol version used by current connection.

Return Values

An unsigned integer representing the protocol version used by the current connection.

Errors

None.

22.8.3.31. `mysql_get_server_info()`

```
const char *mysql_get_server_info(MYSQL *mysql)
```

Description

Returns a string that represents the server version number.

Return Values

A character string that represents the server version number.

Errors

None.

22.8.3.32. `mysql_get_server_version()`

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

Description

Returns the version number of the server as an integer.

Return Values

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.1.5 is returned as 50105.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

Errors

None.

22.8.3.33. `mysql_get_ssl_cipher()`

```
const char *mysql_get_ssl_cipher(MYSQL *mysql)
```

Description

`mysql_get_ssl_cipher()` returns the SSL cipher used for the given connection to the server. `mysql` is the connection handler returned from `mysql_init()`.

Return Values

A string naming the SSL cipher used for the connection, or `NULL` if no cipher is being used.

22.8.3.34. `mysql_hex_string()`

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned long
length)
```

Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 9.1.1, “String Literals”](#).

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0xvalue` or `X'value'` format. However, the return value does not include the `0x` or `X'...`. The caller must supply whichever of those is desired.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What is this",12);
end = strmov(end,"0x");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = '\0';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
        mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

22.8.3.35. `mysql_info()`

```
const char *mysql_info(MYSQL *mysql)
```

Description

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- `INSERT INTO ... SELECT ...`

String format: `Records: 100 Duplicates: 0 Warnings: 0`

- `INSERT INTO ... VALUES (...),(...),(...)...`

String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `LOAD DATA INFILE ...`

String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`

- `ALTER TABLE`

String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `UPDATE`

String format: `Rows matched: 40 Changed: 40 Warnings: 0`

Note that `mysql_info()` returns a non-NULL value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

Return Values

A character string representing additional information about the most recently executed statement. `NULL` if no information is available for the statement.

Errors

None.

22.8.3.36. `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

Description

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

Return Values

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

Errors

In case of insufficient memory, `NULL` is returned.

22.8.3.37. `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that

contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(expr)` [1194].

The return value of `mysql_insert_id()` is always zero unless explicitly updated under one of the following conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit nonspecial value.
- In the case of a multiple-row `INSERT` statement, `mysql_insert_id()` returns the first automatically generated `AUTO_INCREMENT` value that was successfully inserted.

If no rows are successfully inserted, `mysql_insert_id()` returns 0.

- If an `INSERT ... SELECT` statement is executed, and no automatically generated value is successfully inserted, `mysql_insert_id()` returns the ID of the last inserted row.
- If an `INSERT ... SELECT` statement uses `LAST_INSERT_ID(expr)` [1194], `mysql_insert_id()` returns *expr*.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` [1194] into any column or by updating any column to `LAST_INSERT_ID(expr)` [1194].
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

The return value of `mysql_insert_id()` can be simplified to the following sequence:

1. If there is an `AUTO_INCREMENT` column, and an automatically generated value was successfully inserted, return the first such value.
2. If `LAST_INSERT_ID(expr)` [1194] occurred in the statement, return *expr*, even if there was an `AUTO_INCREMENT` column in the affected table.
3. The return value varies depending on the statement used. When called after an `INSERT` statement:
 - If there is an `AUTO_INCREMENT` column in the table, and there were some explicit values for this column that were successfully inserted into the table, return the last of the explicit values.

When called after an `INSERT ... ON DUPLICATE KEY UPDATE` statement:

- If there is an `AUTO_INCREMENT` column in the table and there were some explicit successfully inserted values or some updated values, return the last of the inserted or updated values.

`mysql_insert_id()` returns 0 if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The `LAST_INSERT_ID()` [1194] SQL function will contain the value of the first automatically generated value that was successfully inserted. `LAST_INSERT_ID()` [1194] is not reset between statements because the value of that function is maintained in the server. Another difference from `mysql_insert_id()` is that `LAST_INSERT_ID()` [1194] is not updated if you set an `AUTO_INCREMENT` column to a specific nonspecial value. See [Section 12.14, "Information Functions"](#).

`mysql_insert_id()` returns 0 following a `CALL` statement for a stored procedure that generates an `AUTO_INCREMENT` value because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `LAST_INSERT_ID()` [1194] at the SQL level to obtain the `AUTO_INCREMENT` value.

The reason for the differences between `LAST_INSERT_ID()` [1194] and `mysql_insert_id()` is that `LAST_INSERT_ID()` [1194] is made easy to use in scripts while `mysql_insert_id()` tries to provide more exact information about what happens to the `AUTO_INCREMENT` column.

Return Values

Described in the preceding discussion.

Errors

None.

22.8.3.38. `mysql_kill()`

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

Description

Asks the server to kill the thread specified by `pid`.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `KILL` statement instead.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR` [4030]
The MySQL server has gone away.
- `CR_SERVER_LOST` [4030]
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR` [4029]
An unknown error occurred.

22.8.3.39. `mysql_library_end()`

```
void mysql_library_end(void)
```

Description

This function finalizes the MySQL library. Call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked

to the MySQL client library or the MySQL embedded server library. For a client program linked against the `libmysqlclient` library by using the `-libmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against the `libmysqld` library by using the `-libmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

For usage information, see [Section 22.8.2, “C API Function Overview”](#), and [Section 22.8.3.40, “mysql_library_init\(\)”](#).

22.8.3.40. `mysql_library_init()`

```
int mysql_library_init(int argc, char **argv, char **groups)
```

Description

Call this function to initialize the MySQL library before you call any other MySQL function, whether your application is a regular client program or uses the embedded server. If the application uses the embedded server, this call starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses.

After your application is done using the MySQL library, call `mysql_library_end()` to clean up. See [Section 22.8.3.39, “mysql_library_end\(\)”](#).

The choice of whether the application operates as a regular client or uses the embedded server depends on whether you use the `libmysqlclient` or `libmysqld` library at link time to produce the final executable. For additional information, see [Section 22.8.2, “C API Function Overview”](#).

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. Do this prior to any other client library call.

The `argc` and `argv` arguments are analogous to the arguments to `main()`, and enable passing of options to the embedded server. For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. This is the usual case for applications intended for use only as regular (nonembedded) clients, and the call typically is written as `mysql_library_init(0, NULL, NULL)`.

```
#include <mysql.h>
#include <stdlib.h>

int main(void) {
    if (mysql_library_init(0, NULL, NULL)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */

    mysql_library_end();

    return EXIT_SUCCESS;
}
```

When arguments are to be passed (`argc` is greater than 0), the first element of `argv` is ignored (it typically contains the program name). `mysql_library_init()` makes a copy of the arguments so it is safe to destroy `argv` or `groups` after the call.

For embedded applications, if you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `groups` argument is an array of strings that indicate the groups in option files from which to read options. See [Section 4.2.3.3, “Using Option Files”](#). Make the final entry in the array `NULL`. For convenience, if the `groups` argument itself is `NULL`, the `[server]` and `[embedded]` groups are used by default.

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program",          /* this string is not used */
    "--datadir=.",
    "--key_buffer_size=32M"
};
static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_library_init(sizeof(server_args) / sizeof(char *),
                          server_args, server_groups)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */

    mysql_library_end();

    return EXIT_SUCCESS;
}
```

Return Values

Zero if successful. Nonzero if an error occurred.

22.8.3.41. `mysql_list_dbs()`

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “_”, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW DATABASES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]

Commands were executed in an improper order.

- [CR_OUT_OF_MEMORY \[4030\]](#)

Out of memory.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.42. `mysql_list_fields()`

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

Description

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “_”, or may be a `NULL` pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

It is preferable to use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)

Commands were executed in an improper order.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.43. `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

Description

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR` [4030]
The MySQL server has gone away.
- `CR_SERVER_LOST` [4030]
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR` [4029]
An unknown error occurred.

22.8.3.44. `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters “%” or “_”, or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW TABLES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR` [4030]
The MySQL server has gone away.
- `CR_SERVER_LOST` [4030]

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.45. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

Description

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

`mysql_more_results()` true if more results exist from the currently executed statement, in which case the application must call `mysql_next_result()` to fetch the results.

Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See [Section 22.8.13, “C API Support for Multiple Statement Execution”](#), and [Section 22.8.3.46, “`mysql_next_result\(\)`”](#).

Errors

None.

22.8.3.46. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

Description

This function is used when you execute multiple statements specified as a single statement string, or when you use `CALL` statements to execute stored procedures, which can return multiple result sets.

`mysql_next_result()` reads the next statement result and returns a status to indicate whether more results exist. If `mysql_next_result()` returns an error, there are no more results.

Before each call to `mysql_next_result()`, you must call `mysql_free_result()` for the current statement if it is a statement that returned a result set (rather than just a result status).

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next statement. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL` can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). As of MySQL 5.5.3, `CLIENT_MULTI_RESULTS` is enabled by default.

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_next_result()` to advance to the next result.

For an example that shows how to use `mysql_next_result()`, see [Section 22.8.13, “C API Support for Multiple Statement Execution”](#).

Return Values

| Return Value | Description |
|--------------|--|
| 0 | Successful and there are more results |
| -1 | Successful and there are no more results |
| >0 | An error occurred |

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)

Commands were executed in an improper order. For example, if you didn't call `mysql_use_result()` for a previous result set.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.47. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 22.8.11.1, “Why `mysql_store_result\(\)` Sometimes Returns `NULL` After `mysql_query\(\)` Returns Success”](#).

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```

MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}

```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` returns 0. This happens only if something went wrong.

22.8.3.48. `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_affected_rows()`.

Return Values

The number of rows in the result set.

Errors

None.

22.8.3.49. `mysql_options()`

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const void *arg)
```

Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

Call `mysql_options()` after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, specify a pointer to the value of the integer as the `arg` argument.

The following list describes the possible options, their effect, and how `arg` is used for each option. Several of the options apply only when the application is linked against the `libmysqld` embedded server library and are unused for applications linked against the `libmysql` client library. For option descriptions that indicate `arg` is unused, its value is irrelevant; it is conventional to pass 0.

- `MYSQL_DEFAULT_AUTH` (argument type: `char *`)

The name of the authentication plugin to use. This option was added in MySQL 5.5.7.

- `MYSQL_ENABLE_CLEARTEXT_PLUGIN` (argument type: `my_bool *`)

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.6.4, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.5.27.

- `MYSQL_INIT_COMMAND` (argument type: `char *`)

SQL statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.

- `MYSQL_OPT_COMPRESS` (argument: not used)

Use the compressed client/server protocol.

- `MYSQL_OPT_CONNECT_TIMEOUT` (argument type: `unsigned int *`)

Connect timeout in seconds.

- `MYSQL_OPT_GUESS_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this enables the library to guess whether to use the embedded server or a remote server. “Guess” means that if

the host name is set and is not `localhost`, it uses a remote server. This behavior is the default. `MYSQL_OPT_USE_EMBEDDED_CONNECTION` and `MYSQL_OPT_USE_REMOTE_CONNECTION` can be used to override it. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_LOCAL_INFILE` (argument type: optional pointer to `unsigned int`)

If no pointer is given or if pointer points to an `unsigned int` that has a nonzero value, the `LOAD LOCAL INFILE` statement is enabled.

- `MYSQL_OPT_NAMED_PIPE` (argument: not used)

Use named pipes to connect to a MySQL server on Windows, if the server permits named-pipe connections.

- `MYSQL_OPT_PROTOCOL` (argument type: `unsigned int *`)

Type of protocol to use. Specify one of the enum values of `mysql_protocol_type` defined in `mysql.h`.

- `MYSQL_OPT_READ_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP `Close_Wait_Timeout` value of 10 minutes.

- `MYSQL_OPT_RECONNECT` (argument type: `my_bool *`)

Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect is off by default; this option provides a way to set reconnection behavior explicitly.

- `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` (argument type: `my_bool *`)

Enable or disable verification of the server's Common Name value in its certificate against the host name used when connecting to the server. The connection is rejected if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default.

- `MYSQL_OPT_USE_EMBEDDED_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of the embedded server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_REMOTE_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of a remote server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_RESULT` (argument: not used)

This option is unused.

- `MYSQL_OPT_WRITE_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are `net_retry_count` [532] retries if necessary, so the total effective timeout value is `net_retry_count` [532] times the option value.

- `MYSQL_PLUGIN_DIR`** (argument type: `char *`)
 The directory in which to look for client plugins. This option was added in MySQL 5.5.7.
- `MYSQL_READ_DEFAULT_FILE`** (argument type: `char *`)
 Read options from the named option file instead of from `my.cnf`.
- `MYSQL_READ_DEFAULT_GROUP`** (argument type: `char *`)
 Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.
- `MYSQL_REPORT_DATA_TRUNCATION`** (argument type: `my_bool *`)
 Enable or disable reporting of data truncation errors for prepared statements using the `error` member of `MYSQL_BIND` structures. (Default: enabled.)
- `MYSQL_SECURE_AUTH`** (argument type: `my_bool *`)
 Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.
- `MYSQL_SET_CHARSET_DIR`** (argument type: `char *`)
 The path name to the directory that contains character set definition files.
- `MYSQL_SET_CHARSET_NAME`** (argument type: `char *`)
 The name of the character set to use as the default character set. The argument can be `MYSQL_AUTODETECT_CHARSET_NAME` to cause the character set to be autodetected based on the operating system setting (see [Section 10.1.4, “Connection Character Sets and Collations”](#)).
- `MYSQL_SET_CLIENT_IP`** (argument type: `char *`)
 For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against the `libmysqlclient` client library.
- `MYSQL_SHARED_MEMORY_BASE_NAME`** (argument type: `char *`)
 The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Specify the same value as the `--shared-memory-base-name [460]` option used for the `mysqld` server you want to connect to.

The `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options.

| Option | Description |
|--------------------------------------|--|
| <code>character-sets-dir=path</code> | The directory where character sets are installed. |
| <code>compress</code> | Use the compressed client/server protocol. |
| <code>connect-timeout=seconds</code> | Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server. |

| Option | Description |
|---|--|
| <code>database=db_name</code> | Connect to this database if no database was specified in the connect command. |
| <code>debug</code> | Debug options. |
| <code>default-character-set=charset_name</code> | The default character set to use. |
| <code>disable-local-infile</code> | Disable use of <code>LOAD DATA LOCAL</code> . |
| <code>enable-cleartext-plugin</code> | Enable the <code>mysql_clear_password</code> cleartext authentication plugin. Added in MySQL 5.5.27. |
| <code>host=host_name</code> | Default host name. |
| <code>init-command=stmt</code> | Statement to execute when connecting to MySQL server. Automatically re-executed if reconnection occurs. |
| <code>interactive-timeout=seconds</code> | Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code> . See Section 22.8.3.52 , “ <code>mysql_real_connect()</code> ”. |
| <code>local-infile[={0 1}]</code> | If no argument or nonzero argument, enable use of <code>LOAD DATA LOCAL</code> ; otherwise disable. |
| <code>max_allowed_packet=bytes</code> | Maximum size of packet that client can read from server. |
| <code>multi-queries, multi-results</code> | Enable multiple result sets from multiple-statement executions or stored procedures. |
| <code>multi-statements</code> | Enable the client to send multiple statements in a single string (separated by “;”). |
| <code>password=password</code> | Default password. |
| <code>pipe</code> | Use named pipes to connect to a MySQL server on Windows. |
| <code>port=port_num</code> | Default port number. |
| <code>protocol={TCP SOCKET PIPE MEMORY}</code> | The protocol to use when connecting to the server. |
| <code>return-found-rows</code> | Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code> . |
| <code>shared-memory-base-name=name</code> | Shared-memory name to use to connect to server. |
| <code>socket=path</code> | Default socket file. |
| <code>ssl-ca=file_name</code> | Certificate Authority file. |
| <code>ssl-capath=path</code> | Certificate Authority directory. |
| <code>ssl-cert=file_name</code> | Certificate file. |
| <code>ssl-cipher=cipher_list</code> | Permissible SSL ciphers. |
| <code>ssl-key=file_name</code> | Key file. |
| <code>timeout=seconds</code> | Like <code>connect-timeout</code> . |
| <code>user</code> | Default user. |

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported in MySQL 5.5 for backward compatibility.

For more information about option files, see [Section 4.2.3.3](#), “Using Option Files”.

Return Values

Zero for success. Nonzero if you specify an unknown option.

Example

The following `mysql_options()` calls request the use of compression in the client/server protocol, cause options to be read from the `[odbc]` group of option files, and disable transaction autocommit mode:

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_OPT_COMPRESS,0);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"odbc");
mysql_options(&mysql,MYSQL_INIT_COMMAND,"SET autocommit=0");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr,"Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

This code requests that the client use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

22.8.3.50. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

Description

Checks whether the connection to the server is working. If the connection has gone down and auto-reconnect is enabled an attempt to reconnect is made. If the connection is down and auto-reconnect is disabled, `mysql_ping()` returns an error.

Auto-reconnect is disabled by default. To enable it, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option. For details, see [Section 22.8.3.49, “mysql_options\(\)”](#).

`mysql_ping()` can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

If `mysql_ping()` does cause a reconnect, there is no explicit indication of it. To determine whether a reconnect occurs, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

If reconnect occurs, some characteristics of the connection will have been reset. For details about these characteristics, see [Section 22.8.12, “Controlling Automatic Reconnection Behavior”](#).

Return Values

Zero if the connection to the server is active. Nonzero if an error occurred. A nonzero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.51. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

Description

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement without a terminating semicolon (“;”) or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 22.8.13, “C API Support for Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.)

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 22.8.3.22, “mysql_field_count\(\)”](#).

Return Values

Zero if the statement was successful. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)

Commands were executed in an improper order.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.52. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char *user,  
const char *passwd, const char *db, unsigned int port, const char *unix_socket,  
unsigned long client_flag)
```

Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- For the first parameter, specify the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()`, call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See [Section 22.8.3.49](#), “`mysql_options()`”.
- The value of `host` may be either a host name or an IP address. If `host` is `NULL` or the string “localhost”, a connection to the local host is assumed. For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local connections, you can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server. For a `host` value of “.” on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.
- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string “”, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current user name must be specified explicitly. See the Connector/ODBC section of [Chapter 22, Connectors and APIs](#).
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This enables the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

Note

Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- The `user` and `passwd` parameters use whatever character set has been configured for the `MYSQL` object. By default, this is `latin1`, but can be changed by calling `mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name")` prior to connecting.
- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe to use. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features.

| Flag Name | Flag Description |
|------------------------------------|---|
| <code>CLIENT_COMPRESS</code> | Use compression protocol. |
| <code>CLIENT_FOUND_ROWS</code> | Return the number of found (matched) rows, not the number of changed rows. |
| <code>CLIENT_IGNORE_SIGPIPE</code> | Prevents the client library from installing a <code>SIGPIPE</code> signal handler. This can be used to avoid conflicts with a handler that the application has already installed. |
| <code>CLIENT_IGNORE_SPACE</code> | Permit spaces after function names. Makes all functions names reserved words. |

| Flag Name | Flag Description |
|--------------------------------------|--|
| <code>CLIENT_INTERACTIVE</code> | Permit <code>interactive_timeout</code> [506] seconds (instead of <code>wait_timeout</code> [572] seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> [572] variable is set to the value of the session <code>interactive_timeout</code> [506] variable. |
| <code>CLIENT_LOCAL_FILES</code> | Enable <code>LOAD DATA LOCAL</code> handling. |
| <code>CLIENT_MULTI_RESULTS</code> | Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This flag is automatically enabled if <code>CLIENT_MULTI_STATEMENTS</code> is enabled. See the note following this table for more information about this flag. |
| <code>CLIENT_MULTI_STATEMENTS</code> | Tell the server that the client may send multiple statements in a single string (separated by “;”). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag. |
| <code>CLIENT_NO_SCHEMA</code> | Do not permit the <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs. |
| <code>CLIENT_ODBC</code> | Unused. |
| <code>CLIENT_SSL</code> | Use SSL (encrypted protocol). Do not set this option within an application program; it is set internally in the client library. Instead, use <code>mysql_ssl_set()</code> before calling <code>mysql_real_connect()</code> . |
| <code>CLIENT_REMEMBER_OPTIONS</code> | Remember options specified by calls to <code>mysql_options()</code> . Without this option, if <code>mysql_real_connect()</code> fails, you must repeat the <code>mysql_options()</code> calls before trying to connect again. With this option, the <code>mysql_options()</code> calls need not be repeated. |

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL` can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). As of MySQL 5.5.3, `CLIENT_MULTI_RESULTS` is enabled by default.

If you enable `CLIENT_MULTI_STATEMENTS` or `CLIENT_MULTI_RESULTS`, you should process the result for every call to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 22.8.13, “C API Support for Multiple Statement Execution”](#).

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP` option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the “no-value” value for each parameter to be read from an option file:

- For `host`, specify a value of `NULL` or the empty string (“”).

- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.
- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

Errors

- `CR_CONN_HOST_ERROR` [4030]
Failed to connect to the MySQL server.
- `CR_CONNECTION_ERROR` [4029]
Failed to connect to the local MySQL server.
- `CR_IPSOCK_ERROR` [4030]
Failed to create an IP socket.
- `CR_OUT_OF_MEMORY` [4030]
Out of memory.
- `CR_SOCKET_CREATE_ERROR` [4029]
Failed to create a Unix socket.
- `CR_UNKNOWN_HOST` [4030]
Failed to find the IP address for the host name.
- `CR_VERSION_ERROR` [4030]
A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.
- `CR_NAMEDPIPEOPEN_ERROR` [4030]
Failed to create a named pipe on Windows.
- `CR_NAMEDPIPEWAIT_ERROR` [4030]
Failed to wait for a named pipe on Windows.

- [CR_NAMEDPIPESETSTATE_ERROR \[4031\]](#)
Failed to get a pipe handler on Windows.
- [CR_SERVER_LOST \[4030\]](#)
If [connect_timeout \[492\]](#) > 0 and it took longer than [connect_timeout \[492\]](#) seconds to connect to the server or if the server died while executing the `init-command`.
- [CR_ALREADY_CONNECTED \[4033\]](#)
The `MYSQL` connection handle is already connected.

Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"your_prog_name");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some nonstandard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

22.8.3.53. `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const char
*from, unsigned long length)
```

Note that `mysql` must be a valid, open connection. This is needed because the escaping depends on the character set in use by the server.

Description

This function is used to create a legal SQL string that you can use in an SQL statement. See [Section 9.1.1, “String Literals”](#).

The string in `from` is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in `to` and a terminating null byte is appended. Characters encoded are “\”, “'”, “\”, `NUL` (ASCII 0), “\n”, “\r”, and Control+Z. Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. `mysql_real_escape_string()` quotes the other characters to make them easier to read in log files. For comparison, see the quoting rules for literal strings and the `QUOTE()` [\[1107\]](#) SQL function in [Section 9.1.1, “String Literals”](#), and [Section 12.5, “String Functions”](#).

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When `mysql_real_escape_string()` returns, the

contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

If you need to change the character set of the connection, use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement.

`mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"What is this",12);
*end++ = '\\';
*end++ = ',';
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"binary data: \\0\\r\\n",16);
*end++ = '\\';
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

22.8.3.54. `mysql_real_query()`

```
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long length)
```

Description

Executes the SQL statement pointed to by `stmt_str`, a string `length` bytes long. Normally, the string must consist of a single SQL statement without a terminating semicolon (“;”) or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 22.8.13, “C API Support for Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.) In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the statement string.

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 22.8.3.22, “mysql_field_count\(\)”](#).

Return Values

Zero if the statement was successful. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

22.8.3.55. `mysql_refresh()`

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

Description

This function flushes tables or caches, or resets replication server information. The connected user must have the [RELOAD \[696\]](#) privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- [REFRESH_GRANT](#)
Refresh the grant tables, like [FLUSH PRIVILEGES](#).
- [REFRESH_LOG](#)
Flush the logs, like [FLUSH LOGS](#).
- [REFRESH_TABLES](#)
Flush the table cache, like [FLUSH TABLES](#).
- [REFRESH_HOSTS](#)
Flush the host cache, like [FLUSH HOSTS](#).
- [REFRESH_STATUS](#)
Reset status variables, like [FLUSH STATUS](#).
- [REFRESH_THREADS](#)
Flush the thread cache.
- [REFRESH_SLAVE](#)
On a slave replication server, reset the master server information and restart the slave, like [RESET SLAVE](#).
- [REFRESH_MASTER](#)

On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

22.8.3.56. `mysql_reload()`

```
int mysql_reload(MYSQL *mysql)
```

Description

Asks the MySQL server to reload the grant tables. The connected user must have the `RELOAD [696]` privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `FLUSH PRIVILEGES` statement instead.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

22.8.3.57. `mysql_rollback()`

```
my_bool mysql_rollback(MYSQL *mysql)
```

Description

Rolls back the current transaction.

The action of this function is subject to the value of the `completion_type` [489] system variable. In particular, if the value of `completion_type` [489] is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

Return Values

Zero if successful. Nonzero if an error occurred.

Errors

None.

22.8.3.58. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset, typically a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

Errors

None.

22.8.3.59. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

Description

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

Use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

22.8.3.60. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

Description

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

22.8.3.61. `mysql_set_character_set()`

```
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

Return Values

Zero for success. Nonzero if an error occurred.

Example

```
MYSQL mysql;
```

```
mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}

if (!mysql_set_character_set(&mysql, "utf8"))
{
    printf("New client character set: %s\n",
            mysql_character_set_name(&mysql));
}
```

22.8.3.62. `mysql_set_local_infile_default()`

```
void mysql_set_local_infile_default(MYSQL *mysql);
```

Description

Sets the `LOAD LOCAL DATA INFILE` handler callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

Return Values

None.

Errors

None.

22.8.3.63. `mysql_set_local_infile_handler()`

```
void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)(void
**, const char *, void *), int (*local_infile_read)(void *, char *, unsigned
int), void (*local_infile_end)(void *), int (*local_infile_error)(void *,
char*, unsigned int), void *userdata);
```

Description

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables application programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

The initialization function should return zero for success, nonzero for an error.

```
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data is stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. Within this function, deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```
int
local_infile_error(void *ptr,
                  char *error_msg,
                  unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message is written, and `error_msg_len` is the length of the buffer. Write the message as a null-terminated string, at most `error_msg_len-1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The file name specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

Return Values

None.

Errors

None.

22.8.3.64. `mysql_set_server_option()`

```
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)
```

Description

Enables or disables an option for the connection. `option` can have one of the following values.

| Option | Description |
|--|------------------------------------|
| <code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code> | Enable multiple-statement support |
| <code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code> | Disable multiple-statement support |

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 22.8.13, “C API Support for Multiple Statement Execution”](#).

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`: `CLIENT_MULTI_STATEMENTS` also enables `CLIENT_MULTI_RESULTS`. If you are using the `CALL` SQL statement in your programs, multiple-result support must be enabled; this means that `MYSQL_OPTION_MULTI_STATEMENTS_ON` by itself is insufficient to permit the use of `CALL`.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)

Commands were executed in an improper order.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query.

- [ER_UNKNOWN_COM_ERROR \[3982\]](#)

The server didn't support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

22.8.3.65. `mysql_shutdown()`

```
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

Description

Asks the database server to shut down. The connected user must have the [SHUTDOWN \[697\]](#) privilege. MySQL 5.5 servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Additional shutdown levels are planned to make it possible to choose the desired level. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in [Section 5.1.12, "The Shutdown Process"](#).

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)

Commands were executed in an improper order.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.66. `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

Description

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. '00000' means “no error.” The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix C, Errors, Error Codes, and Common Problems](#).

SQLSTATE values returned by `mysql_sqlstate()` differ from MySQL-specific error numbers returned by `mysql_errno()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped error numbers.

If you call `mysql_sqlstate()` after `mysql_real_connect()` fails, `mysql_sqlstate()` might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

Return Values

A null-terminated character string containing the SQLSTATE error code.

See Also

See [Section 22.8.3.14, “mysql_errno\(\)”](#), [Section 22.8.3.15, “mysql_error\(\)”](#), and [Section 22.8.7.27, “mysql_stmt_sqlstate\(\)”](#).

22.8.3.67. `mysql_ssl_set()`

```
my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const
char *ca, const char *capath, const char *cipher)
```

Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless SSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the path name to the key file.

- `cert` is the path name to the certificate file.
- `ca` is the path name to the certificate authority file.
- `capath` is the path name to a directory that contains trusted SSL CA certificates in PEM format.
- `cipher` is a list of permissible ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

Return Values

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

22.8.3.68. `mysql_stat()`

```
const char *mysql_stat(MYSQL *mysql)
```

Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

Return Values

A character string describing the server status. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC [4030]`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR [4030]`
The MySQL server has gone away.
- `CR_SERVER_LOST [4030]`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR [4029]`
An unknown error occurred.

22.8.3.69. `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a nonzero value (more about this later).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 22.8.13, "C API Support for Multiple Statement Execution"](#).

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 22.8.3.22, "mysql_field_count\(\)"](#).

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the statement didn't return a result set (for example, if it was an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking whether `mysql_error()` returns a nonempty string, `mysql_errno()` returns nonzero, or `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that isn't a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

See [Section 22.8.11.1, "Why mysql_store_result\(\) Sometimes Returns NULL After mysql_query\(\) Returns Success"](#).

Return Values

A `MYSQL_RES` result structure with the results. `NULL` (0) if an error occurred.

Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC` [4030]

Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY` [4030]

Out of memory.

- `CR_SERVER_GONE_ERROR` [4030]

The MySQL server has gone away.

- `CR_SERVER_LOST` [4030]

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.3.70. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

Note

This function does not work correctly if thread IDs become larger than 32 bits, which can occur on some systems. To avoid problems with `mysql_thread_id()`, do not use it. To get the connection ID, execute a `SELECT CONNECTION_ID()` query and retrieve the result.

Return Values

The thread ID of the current connection.

Errors

None.

22.8.3.71. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet [519]` bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the un fetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC` [4030]

Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY` [4030]

Out of memory.

- `CR_SERVER_GONE_ERROR` [4030]

The MySQL server has gone away.

- `CR_SERVER_LOST` [4030]

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR` [4029]

An unknown error occurred.

22.8.3.72. `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

Description

Returns the number of errors, warnings, and notes generated during execution of the previous SQL statement.

Return Values

The warning count.

Errors

None.

22.8.4. C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and nonprepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

The following SQL statements can be used as prepared statements:

```
CALL
CREATE TABLE
DELETE
DO
INSERT
REPLACE
SELECT
SET
UPDATE
ANALYZE TABLE
OPTIMIZE TABLE
REPAIR TABLE
CACHE INDEX
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
{CREATE | RENAME | DROP} DATABASE
{CREATE | RENAME | DROP} USER
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
REVOKE
KILL
LOAD INDEX INTO CACHE
RESET {MASTER | SLAVE | QUERY CACHE}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
INSTALL PLUGIN
UNINSTALL PLUGIN
```

Other statements are not yet supported in MySQL 5.5.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 13.5.4, “Automatic Prepared Statement Reparation”](#).

22.8.5. C API Prepared Statement Data Structures

Prepared statements use several data structures:

- To obtain a statement handle, pass a `MYSQL` connection handler to `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT` data structure. This structure is used for further operations with the statement. To specify the statement to prepare, pass the `MYSQL_STMT` pointer and the statement string to `mysql_stmt_prepare()`.
- To provide input parameters for a prepared statement, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_param()`. To receive output column values, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_result()`.
- The `MYSQL_TIME` structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail. For examples that show how to use them, see [Section 22.8.7.10](#), “`mysql_stmt_execute()`”, and [Section 22.8.7.11](#), “`mysql_stmt_fetch()`”.

- `MYSQL_STMT`

This structure is a handle for a prepared statement. A handle is created by calling `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT`. The handle is used for all subsequent operations with the statement until you close it with `mysql_stmt_close()`, at which point the handle becomes invalid.

The `MYSQL_STMT` structure has no members intended for application use. Applications should not try to copy a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

- For input, use `MYSQL_BIND` structures with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`.
- For output, use `MYSQL_BIND` structures with `mysql_stmt_bind_result()` to bind buffers to result set columns, for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, zero its contents to initialize it, then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

- `enum enum_field_types buffer_type`

The type of the buffer. This member indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored. For permissible `buffer_type` values, see [Section 22.8.5.1](#), “C API Prepared Statement Type Codes”.

- `void *buffer`

A pointer to the buffer to be used for data transfer. This is the address of a C language variable.

For input, `buffer` is a pointer to the variable in which you store the data value for a statement parameter. When you call `mysql_stmt_execute()`, MySQL use the value stored in the variable in place of the corresponding parameter marker in the statement (specified with `?` in the statement string).

For output, `buffer` is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL stores a column value from the current row of the result set in this variable. You can access the value when the call returns.

To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use C variables that have types similar to those of the corresponding SQL values:

- For numeric data types, `buffer` should point to a variable of the proper numeric C type. For integer variables (which can be `char` for single-byte values or an integer type for larger values), you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later.
- For character (nonbinary) and binary string data types, `buffer` should point to a character buffer.
- For date and time data types, `buffer` should point to a `MYSQL_TIME` structure.

For guidelines about mapping between C types and SQL types and notes about type conversions, see [Section 22.8.5.1, “C API Prepared Statement Type Codes”](#), and [Section 22.8.5.2, “C API Prepared Statement Type Conversions”](#).

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data.

For input parameter data binding, set `*length` to indicate the actual length of the parameter value stored in `*buffer`. This is used by `mysql_stmt_execute()`.

For output value binding, MySQL sets `*length` when you call `mysql_stmt_fetch()`. The `mysql_stmt_fetch()` return value determines how to interpret the length:

- If the return value is 0, `*length` indicates the actual length of the parameter value.
- If the return value is `MYSQL_DATA_TRUNCATED`, `*length` indicates the nontruncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

`length` is ignored for numeric and temporal data types because the `buffer_type` value determines the length of the data value.

If you must determine the length of a returned value before fetching it, see [Section 22.8.7.11](#), “`mysql_stmt_fetch()`”, for some strategies.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter.

`is_null` is a *pointer* to a boolean scalar, not a boolean scalar, to provide flexibility in how you specify `NULL` values:

- If your data values are always `NULL`, use `MYSQL_TYPE_NULL` as the `buffer_type` value when you bind the column. The other `MYSQL_BIND` members, including `is_null`, do not matter.
- If your data values are always `NOT NULL`, set `is_null = (my_bool*) 0`, and set the other members appropriately for the variable you are binding.
- In all other cases, set the other members appropriately and set `is_null` to the address of a `my_bool` variable. Set that variable's value to true or false appropriately between executions to indicate whether the corresponding data value is `NULL` or `NOT NULL`, respectively.

For output, when you fetch a row, MySQL sets the value pointed to by `is_null` to true or false according to whether the result set column value returned from the statement is or is not `NULL`.

- `my_bool is_unsigned`

This member applies for C variables with data types that can be `unsigned` (`char`, `short int`, `int`, `long long int`). Set `is_unsigned` to true if the variable pointed to by `buffer` is `unsigned` and false otherwise. For example, if you bind a `signed char` variable to `buffer`, specify a type code of `MYSQL_TYPE_TINY` and set `is_unsigned` to false. If you bind an `unsigned char` instead, the type code is the same but `is_unsigned` should be true. (For `char`, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using `signed char` or `unsigned char`.)

`is_unsigned` applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an `int` variable to supply a value for a `BIGINT UNSIGNED` column, `is_unsigned` should be false because `int` is a signed type. If you use an `unsigned int` variable to supply a value for a `BIGINT` column, `is_unsigned` should be true because `unsigned int` is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

- `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. When truncation reporting is enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. Set the `buffer` member to point to a `MYSQL_TIME` structure, and set the

`buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types (`MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATE`, `MYSQL_TYPE_DATETIME`, `MYSQL_TYPE_TIMESTAMP`).

The `MYSQL_TIME` structure contains the members listed in the following table.

| Member | Description |
|--|---|
| <code>unsigned int year</code> | The year |
| <code>unsigned int month</code> | The month of the year |
| <code>unsigned int day</code> | The day of the month |
| <code>unsigned int hour</code> | The hour of the day |
| <code>unsigned int minute</code> | The minute of the hour |
| <code>unsigned int second</code> | The second of the minute |
| <code>my_bool neg</code> | A boolean flag indicating whether the time is negative |
| <code>unsigned long second_part</code> | The fractional part of the second in microseconds; currently unused |

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used. The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See [Section 22.8.15, “C API Prepared Statement Handling of Date and Time Values”](#).

22.8.5.1. C API Prepared Statement Type Codes

The `buffer_type` member of `MYSQL_BIND` structures indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for input values sent to the server. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

| Input Variable C Type | <code>buffer_type</code> Value | SQL Type of Destination Value |
|----------------------------|-----------------------------------|--|
| <code>signed char</code> | <code>MYSQL_TYPE_TINY</code> | <code>TINYINT</code> |
| <code>short int</code> | <code>MYSQL_TYPE_SHORT</code> | <code>SMALLINT</code> |
| <code>int</code> | <code>MYSQL_TYPE_LONG</code> | <code>INT</code> |
| <code>long long int</code> | <code>MYSQL_TYPE_LONGLONG</code> | <code>BIGINT</code> |
| <code>float</code> | <code>MYSQL_TYPE_FLOAT</code> | <code>FLOAT</code> |
| <code>double</code> | <code>MYSQL_TYPE_DOUBLE</code> | <code>DOUBLE</code> |
| <code>MYSQL_TIME</code> | <code>MYSQL_TYPE_TIME</code> | <code>TIME</code> |
| <code>MYSQL_TIME</code> | <code>MYSQL_TYPE_DATE</code> | <code>DATE</code> |
| <code>MYSQL_TIME</code> | <code>MYSQL_TYPE_DATETIME</code> | <code>DATETIME</code> |
| <code>MYSQL_TIME</code> | <code>MYSQL_TYPE_TIMESTAMP</code> | <code>TIMESTAMP</code> |
| <code>char[]</code> | <code>MYSQL_TYPE_STRING</code> | <code>TEXT</code> , <code>CHAR</code> , <code>VARCHAR</code> |

| Input Variable C Type | buffer_type Value | SQL Type of Destination Value |
|-----------------------|-------------------|-------------------------------|
| char[] | MYSQL_TYPE_BLOB | BLOB, BINARY, VARBINARY |
| | MYSQL_TYPE_NULL | NULL |

Use `MYSQL_TYPE_NULL` as indicated in the description for the `is_null` member in [Section 22.8.5, “C API Prepared Statement Data Structures”](#).

For input string data, use `MYSQL_TYPE_STRING` or `MYSQL_TYPE_BLOB` depending on whether the value is a character (nonbinary) or binary string:

- `MYSQL_TYPE_STRING` indicates character input string data. The value is assumed to be in the character set indicated by the `character_set_client` [486] system variable. If the server stores the value into a column with a different character set, it converts the value to that character set.
- `MYSQL_TYPE_BLOB` indicates binary input string data. The value is treated as having the `binary` character set. That is, it is treated as a byte string and no conversion occurs.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for output values received from the server. The table shows the SQL types of received values, the corresponding type codes that such values have in result set metadata, and the recommended C language data types to bind to the `MYSQL_BIND` structure to receive the SQL values without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

| SQL Type of Received Value | buffer_type Value | Output Variable C Type |
|----------------------------|------------------------|------------------------|
| TINYINT | MYSQL_TYPE_TINY | signed char |
| SMALLINT | MYSQL_TYPE_SHORT | short int |
| MEDIUMINT | MYSQL_TYPE_INT24 | int |
| INT | MYSQL_TYPE_LONG | int |
| BIGINT | MYSQL_TYPE_LONGLONG | long long int |
| FLOAT | MYSQL_TYPE_FLOAT | float |
| DOUBLE | MYSQL_TYPE_DOUBLE | double |
| DECIMAL | MYSQL_TYPE_NEWDECIMAL | char[] |
| YEAR | MYSQL_TYPE_SHORT | short int |
| TIME | MYSQL_TYPE_TIME | MYSQL_TIME |
| DATE | MYSQL_TYPE_DATE | MYSQL_TIME |
| DATETIME | MYSQL_TYPE_DATETIME | MYSQL_TIME |
| TIMESTAMP | MYSQL_TYPE_TIMESTAMP | MYSQL_TIME |
| CHAR, BINARY | MYSQL_TYPE_STRING | char[] |
| VARCHAR, VARBINARY | MYSQL_TYPE_VAR_STRING | char[] |
| TINYBLOB, TINYTEXT | MYSQL_TYPE_TINY_BLOB | char[] |
| BLOB, TEXT | MYSQL_TYPE_BLOB | char[] |
| MEDIUMBLOB, MEDIUMTEXT | MYSQL_TYPE_MEDIUM_BLOB | char[] |
| LONGBLOB, LONGTEXT | MYSQL_TYPE_LONG_BLOB | char[] |
| BIT | MYSQL_TYPE_BIT | char[] |

22.8.5.2. C API Prepared Statement Type Conversions

Prepared statements transmit data between the client and server using C language variables on the client side that correspond to SQL values on the server side. If there is a mismatch between the C variable type on the client side and the corresponding SQL value type on the server side, MySQL performs implicit type conversions in both directions.

MySQL knows the type code for the SQL value on the server side. The `buffer_type` value in the `MYSQL_BIND` structure indicates the type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use `MYSQL_TYPE_LONG` with an `int` variable to pass an integer value to the server that is to be stored into a `FLOAT` column, MySQL converts the value to floating-point format before storing it.
- If you fetch an SQL `MEDIUMINT` column value, but specify a `buffer_type` value of `MYSQL_TYPE_LONGLONG` and use a C variable of type `long long int` as the destination buffer, MySQL converts the `MEDIUMINT` value (which requires less than 8 bytes) for storage into the `long long int` (an 8-byte variable).
- If you fetch a numeric column with a value of 255 into a `char[4]` character array and specify a `buffer_type` value of `MYSQL_TYPE_STRING`, the resulting value in the array is a 4-byte string `'255\0'`.
- MySQL returns `DECIMAL` values as the string representation of the original server-side value, which is why the corresponding C type is `char[]`. For example, `12.345` is returned to the client as `'12.345'`. If you specify `MYSQL_TYPE_NEWDECIMAL` and bind a string buffer to the `MYSQL_BIND` structure, `mysql_stmt_fetch()` stores the value in the buffer as a string without conversion. If instead you specify a numeric variable and type code, `mysql_stmt_fetch()` converts the string-format `DECIMAL` value to numeric form.
- For the `MYSQL_TYPE_BIT` type code, `BIT` values are returned into a string buffer, which is why the corresponding C type is `char[]`. The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

```
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
```

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the `MYSQL_BIND` structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call `mysql_stmt_result_metadata()` after executing the prepared statement with `mysql_stmt_execute()`. The metadata provides access to the type codes for the result set as described in [Section 22.8.7.23, “mysql_stmt_result_metadata\(\)”](#), and [Section 22.8.1, “C API Data Structures”](#).

To determine whether output string values in a result set returned from the server contain binary or nonbinary data, check whether the `charsetnr` value of the result set metadata is 63 (see [Section 22.8.1, “C API Data Structures”](#)). If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

If you cause the `max_length` member of the `MYSQL_FIELD` column metadata structures to be set (by calling `mysql_stmt_attr_set()`), be aware that the `max_length` values for the result set

indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, `max_length` does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. Choose the size of the buffers according to the types of the variables into which you fetch the values. For example, a `TINYINT` column containing the value -128 might have a `max_length` value of 4. But the binary representation of any `TINYINT` value requires only 1 byte for storage, so you can supply a `signed char` variable in which to store the value and set `is_unsigned` to indicate that values are signed.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 13.5.4, “Automatic Prepared Statement Reparation”](#).

22.8.6. C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See [Section 22.8.7, “C API Prepared Statement Function Descriptions”](#).

| Function | Description |
|--|---|
| <code>mysql_stmt_affected_rows()</code> | Returns the number of rows changed, deleted, or inserted by prepared <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> statement |
| <code>mysql_stmt_attr_get()</code> | Gets value of an attribute for a prepared statement |
| <code>mysql_stmt_attr_set()</code> | Sets an attribute for a prepared statement |
| <code>mysql_stmt_bind_param()</code> | Associates application data buffers with the parameter markers in a prepared SQL statement |
| <code>mysql_stmt_bind_result()</code> | Associates application data buffers with columns in a result set |
| <code>mysql_stmt_close()</code> | Frees memory used by a prepared statement |
| <code>mysql_stmt_data_seek()</code> | Seeks to an arbitrary row number in a statement result set |
| <code>mysql_stmt_errno()</code> | Returns the error number for the last statement execution |
| <code>mysql_stmt_error()</code> | Returns the error message for the last statement execution |
| <code>mysql_stmt_execute()</code> | Executes a prepared statement |
| <code>mysql_stmt_fetch()</code> | Fetches the next row of data from a result set and returns data for all bound columns |
| <code>mysql_stmt_fetch_column()</code> | Fetch data for one column of the current row of a result set |
| <code>mysql_stmt_field_count()</code> | Returns the number of result columns for the most recent statement |
| <code>mysql_stmt_free_result()</code> | Free the resources allocated to a statement handle |
| <code>mysql_stmt_init()</code> | Allocates memory for a <code>MYSQL_STMT</code> structure and initializes it |
| <code>mysql_stmt_insert_id()</code> | Returns the ID generated for an <code>AUTO_INCREMENT</code> column by a prepared statement |
| <code>mysql_stmt_next_result()</code> | Returns/initiates the next result in a multiple-result execution |
| <code>mysql_stmt_num_rows()</code> | Returns the row count from a buffered statement result set |
| <code>mysql_stmt_param_count()</code> | Returns the number of parameters in a prepared statement |
| <code>mysql_stmt_param_metadata()</code> | (Return parameter metadata in the form of a result set) Currently, this function does nothing |
| <code>mysql_stmt_prepare()</code> | Prepares an SQL statement string for execution |
| <code>mysql_stmt_reset()</code> | Resets the statement buffers in the server |

| Function | Description |
|---|---|
| <code>mysql_stmt_result_metadata()</code> | Returns prepared statement metadata in the form of a result set |
| <code>mysql_stmt_row_seek()</code> | Seeks to a row offset in a statement result set, using value returned from <code>mysql_stmt_row_tell()</code> |
| <code>mysql_stmt_row_tell()</code> | Returns the statement row cursor position |
| <code>mysql_stmt_send_long_data()</code> | Sends long data in chunks to server |
| <code>mysql_stmt_sqlstate()</code> | Returns the SQLSTATE error code for the last statement execution |
| <code>mysql_stmt_store_result()</code> | Retrieves a complete result set to the client |

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare the statement string, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

You can send text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See [Section 22.8.7.26](#), “`mysql_stmt_send_long_data()`”.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

When statement execution has been completed, close the statement handle using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement will produce a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.
3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and the number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the current row of the result set and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error number, error message, and SQLSTATE code using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string `"SELECT ?"`.
2. Call `mysql_stmt_bind_param()` to bind the value `3` to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare [1] SELECT ?
Execute [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` lines shows a prepared statement after substitution of data values for `?` parameters.

22.8.7. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

22.8.7.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_affected_rows()` may be called immediately after executing a statement with `mysql_stmt_execute()`. It is like `mysql_affected_rows()` but for prepared statements. For a description of what the affected-rows value returned by this function means, See [Section 22.8.3.1](#), “`mysql_affected_rows()`”.

Errors

None.

Example

See the Example in [Section 22.8.7.10](#), “`mysql_stmt_execute()`”.

22.8.7.2. `mysql_stmt_attr_get()`

```
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type option,
void *arg)
```

Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, `arg` should point to the value of the integer.

See [Section 22.8.7.3](#), “`mysql_stmt_attr_set()`”, for a list of options and option types.

Return Values

Zero if successful. Nonzero if `option` is unknown.

Errors

None.

22.8.7.3. `mysql_stmt_attr_set()`

```
my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type option,
const void *arg)
```

Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set. The `arg` argument is the value for the option. `arg` should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

The following table shows the possible `option` values.

| Option | Argument Type | Function |
|--|------------------------|---|
| <code>STMT_ATTR_UPDATE_MAX_LENGTH</code> | <code>my_bool *</code> | If set to 1, causes <code>mysql_stmt_store_result()</code> to |

| Option | Argument Type | Function |
|--------------------------------------|-----------------|---|
| | | update the metadata <code>MYSQL_FIELD->max_length</code> value. |
| <code>STMT_ATTR_CURSOR_TYPE</code> | unsigned long * | Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. <code>*arg</code> can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code> . |
| <code>STMT_ATTR_PREFETCH_ROWS</code> | unsigned long * | Number of rows to fetch from server at a time when using a cursor. <code>*arg</code> can be in the range from 1 to the maximum value of <code>unsigned long</code> . The default is 1. |

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

Return Values

Zero if successful. Nonzero if `option` is unknown.

Errors

None.

Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                        (void*) &prefetch_rows);
/* ... check return value ... */
```

22.8.7.4. `mysql_stmt_bind_param()`

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_param()` is used to bind input data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind`

is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each “?” parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

[Section 22.8.5, “C API Prepared Statement Data Structures”](#), describes the members of each `MYSQL_BIND` element and how they should be set to provide input values.

Return Values

Zero if the bind operation was successful. Nonzero if an error occurred.

Errors

- [CR_UNSUPPORTED_PARAM_TYPE \[4032\]](#)

The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- [CR_OUT_OF_MEMORY \[4030\]](#)

Out of memory.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

Example

See the Example in [Section 22.8.7.10, “mysql_stmt_execute\(\)”](#).

22.8.7.5. `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. [Section 22.8.5, “C API Prepared Statement Data Structures”](#), describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

Return Values

Zero if the bind operation was successful. Nonzero if an error occurred.

Errors

- [CR_UNSUPPORTED_PARAM_TYPE \[4032\]](#)

The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- [CR_OUT_OF_MEMORY \[4030\]](#)

Out of memory.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

Example

See the Example in [Section 22.8.7.11, “mysql_stmt_fetch\(\)”](#).

22.8.7.6. `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

Return Values

Zero if the statement was freed successfully. Nonzero if an error occurred.

Errors

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

Example

See the Example in [Section 22.8.7.10, “mysql_stmt_execute\(\)”](#).

22.8.7.7. `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

None.

Errors

None.

22.8.7.8. `mysql_stmt_errno()`

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix C, Errors, Error Codes, and Common Problems](#).

Return Values

An error code value. Zero if no error occurred.

Errors

None.

22.8.7.9. `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (" ") is returned if no error occurred. This means the following two tests are equivalent:

```
if(*mysql_stmt_errno(stmt))
{
    // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages.

Return Values

A character string that describes the error. An empty string if no error occurred.

Errors

None.

22.8.7.10. `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

Statement processing following `mysql_stmt_execute()` depends on the type of statement:

- For an `UPDATE`, `DELETE`, or `INSERT`, the number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`.
- For a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to [Section 22.8.7.11, “mysql_stmt_fetch\(\)”](#).

Do not following invocation of `mysql_stmt_execute()` with a call to `mysql_store_result()` or `mysql_use_result()`. Those functions are not intended for processing results from prepared statements.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 13.5.4, “Automatic Prepared Statement Reparation”](#).

Return Values

Zero if execution was successful. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY` [4030]
Out of memory.
- `CR_SERVER_GONE_ERROR` [4030]
The MySQL server has gone away.
- `CR_SERVER_LOST` [4030]
The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle. For an example that shows how to retrieve data, see [Section 22.8.7.11](#), "`mysql_stmt_fetch()`".

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(coll INT,\
                                col2 VARCHAR(40),\
                                col3 SMALLINT,\
                                col4 TIMESTAMP)"

#define INSERT_SAMPLE "INSERT INTO \
                        test_table(coll,col2,col3) \
                        VALUES(?,?,?)"

MYSQL_STMT    *stmt;
MYSQL_BIND    bind[3];
my_ulonglong  affected_rows;
int           param_count;
short        small_data;
int          int_data;
char         str_data[STRING_SIZE];
unsigned long str_length;
my_bool      is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
    fprintf(stderr, " DROP TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
    fprintf(stderr, " CREATE TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/* sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), INSERT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
fprintf(stdout, " prepare, INSERT successful\n");

/* Get the parameter count from the statement */
```

```
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in INSERT: %d\n", param_count);

if (param_count != 3) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Bind the data for all 3 parameters */

memset(bind, 0, sizeof(bind));

/* INTEGER PARAM */
/* This is a number type, so there is no need
   to specify buffer_length */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= 0;
bind[0].length= 0;

/* STRING PARAM */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= 0;

str_length= strlen(str_data);

/* INSERT SMALLINT data as NULL */
is_null= 1;

/* Execute the INSERT statement - 1*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute(), 1 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}
```

```

}

/* Specify data values for second row,
   then re-execute the statement */
int_data= 1000;
strncpy(str_data, "
        The most popular Open Source database",
        STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000;      /* smallint */
is_null= 0;          /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

Note

For complete examples on the use of prepared statement functions, refer to the file [tests/mysql_client_test.c](#). This file can be obtained from a MySQL source distribution or from the Bazaar source repository.

22.8.7.11. [mysql_stmt_fetch\(\)](#)

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

Description

[mysql_stmt_fetch\(\)](#) returns the next row in the result set. It can be called only while the result set exists; that is, after a call to [mysql_stmt_execute\(\)](#) for a statement such as `SELECT` that produces a result set.

[mysql_stmt_fetch\(\)](#) returns row data using the buffers bound by [mysql_stmt_bind_result\(\)](#). It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer. All columns must be bound by the application before it calls [mysql_stmt_fetch\(\)](#).

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call [mysql_stmt_store_result\(\)](#) after binding the data buffers and before calling [mysql_stmt_fetch\(\)](#).

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains `TRUE` (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

| Type | Length |
|----------------------------------|---------------------------------|
| <code>MYSQL_TYPE_TINY</code> | 1 |
| <code>MYSQL_TYPE_SHORT</code> | 2 |
| <code>MYSQL_TYPE_LONG</code> | 4 |
| <code>MYSQL_TYPE_LONGLONG</code> | 8 |
| <code>MYSQL_TYPE_FLOAT</code> | 4 |
| <code>MYSQL_TYPE_DOUBLE</code> | 8 |
| <code>MYSQL_TYPE_TIME</code> | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_DATE</code> | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_DATETIME</code> | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_STRING</code> | <code>data length</code> |
| <code>MYSQL_TYPE_BLOB</code> | <code>data_length</code> |

In some cases you might want to determine the length of a column value before fetching it with `mysql_stmt_fetch()`. For example, the value might be a long string or `BLOB` value for which you want to know how much space must be allocated. To accomplish this, you can use these strategies:

- Before invoking `mysql_stmt_fetch()` to retrieve individual rows, pass `STMT_ATTR_UPDATE_MAX_LENGTH` to `mysql_stmt_attr_set()`, then invoke `mysql_stmt_store_result()` to buffer the entire result on the client side. Setting the `STMT_ATTR_UPDATE_MAX_LENGTH` attribute causes the maximal length of column values to be indicated by the `max_length` member of the result set metadata returned by `mysql_stmt_result_metadata()`.
- Invoke `mysql_stmt_fetch()` with a zero-length buffer for the column in question and a pointer in which the real length can be stored. Then use the real length with `mysql_stmt_fetch_column()`.

```
real_length= 0;

bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length
mysql_stmt_bind_result(stmt, bind);

mysql_stmt_fetch(stmt);
if (real_length > 0)
{
    data= malloc(real_length);
    bind[0].buffer= data;
    bind[0].buffer_length= real_length;
    mysql_stmt_fetch_column(stmt, bind, 0, 0);
}
```

Return Values

| Return Value | Description |
|--------------|--|
| 0 | Successful, the data has been fetched to application data buffers. |

| Return Value | Description |
|-----------------------------------|---|
| 1 | Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> . |
| <code>MYSQL_NO_DATA</code> | No more rows/data exists |
| <code>MYSQL_DATA_TRUNCATED</code> | Data truncation occurred |

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. To determine which column values were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` structures used for fetching values. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY` [4030]
Out of memory.
- `CR_SERVER_GONE_ERROR` [4030]
The MySQL server has gone away.
- `CR_SERVER_LOST` [4030]
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR` [4029]
An unknown error occurred.
- `CR_UNSUPPORTED_PARAM_TYPE` [4032]
The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.
- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in [Section 22.8.7.10](#), “`mysql_stmt_execute()`”). The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \
                      FROM test_table"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[4];
MYSQL_RES       *prepare_meta_result;
MYSQL_TIME      ts;
unsigned long   length[4];
int             param_count, column_count, row_count;
short          small_data;
```

```
int         int_data;
char        str_data[STRING_SIZE];
my_bool     is_null[4];
my_bool     error[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
fprintf(stdout, " prepare, SELECT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in SELECT: %d\n", param_count);

if (param_count != 0) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{
    fprintf(stderr,
            " mysql_stmt_result_metadata(), \
            returned no meta information\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get total columns in the query */
column_count= mysql_num_fields(prepare_meta_result);
fprintf(stdout,
        " total columns in SELECT statement: %d\n",
        column_count);

if (column_count != 4) /* validate column count */
{
    fprintf(stderr, " invalid column count returned by MySQL\n");
    exit(0);
}

/* Execute the SELECT query */
if (mysql_stmt_execute(stmt))

    fprintf(stderr, "%s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Fetch all rows */
row_count= 0;
fprintf(stdout, "Fetching results ...\n");
while (!mysql_stmt_fetch(stmt))
{
    row_count++;
    fprintf(stdout, " row %d\n", row_count);

    /* column 1 */
    fprintf(stdout, " column1 (integer) : ");
    if (is_null[0])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %d(%ld)\n", int_data, length[0]);

    /* column 2 */
    fprintf(stdout, " column2 (string) : ");
    if (is_null[1])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %s(%ld)\n", str_data, length[1]);

    /* column 3 */
    fprintf(stdout, " column3 (smallint) : ");
```

```

if (is_null[2])
    fprintf(stdout, " NULL\n");
else
    fprintf(stdout, "%d(%ld)\n", small_data, length[2]);

/* column 4 */
fprintf(stdout, "    column4 (timestamp): ");
if (is_null[3])
    fprintf(stdout, " NULL\n");
else
    fprintf(stdout, "%04d-%02d-%02d %02d:%02d:%02d (%ld)\n",
              ts.year, ts.month, ts.day,
              ts.hour, ts.minute, ts.second,
              length[3]);
fprintf(stdout, "\n");
}

/* Validate rows fetched */
fprintf(stdout, " total rows fetched: %d\n", row_count);
if (row_count != 2)
{
    fprintf(stderr, " MySQL failed to return all rows\n");
    exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

22.8.7.12. `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int
column, unsigned long offset)
```

Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

Return Values

Zero if the value was fetched successfully. Nonzero if an error occurred.

Errors

- [CR_INVALID_PARAMETER_NO \[4032\]](#)
Invalid column number.
- [CR_NO_DATA \[4033\]](#)
The end of the result set has already been reached.

22.8.7.13. `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

22.8.7.14. `mysql_stmt_free_result()`

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

Return Values

Zero if the result set was freed successfully. Nonzero if an error occurred.

Errors

22.8.7.15. `mysql_stmt_init()`

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

Description

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

See also [Section 22.8.5, “C API Prepared Statement Data Structures”](#), for more information.

Return Values

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

Errors

- `CR_OUT_OF_MEMORY` [4030]

Out of memory.

22.8.7.16. `mysql_stmt_insert_id()`

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

Description

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed a prepared `INSERT` statement on a table which contains an `AUTO_INCREMENT` field.

See [Section 22.8.3.37](#), “`mysql_insert_id()`”, for more information.

Return Values

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` [1194] function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

Errors

None.

22.8.7.17. `mysql_stmt_next_result()`

```
int mysql_stmt_next_result(MYSQL_STMT *mysql)
```

Description

This function is used when you use prepared `CALL` statements to execute stored procedures, which can return multiple result sets. Use a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. If a procedure has `OUT` or `INOUT` parameters, their values will be returned as a single-row result set following any other result sets. The values will appear in the order in which they are declared in the procedure parameter list.

`mysql_stmt_next_result()` returns a status to indicate whether more results exist. If `mysql_stmt_next_result()` returns an error, there are no more results.

Before each call to `mysql_stmt_next_result()`, you must call `mysql_stmt_free_result()` for the current result if it produced a result set (rather than just a result status).

After calling `mysql_stmt_next_result()` the state of the connection is as if you had called `mysql_stmt_execute()`. This means that you can call `mysql_stmt_bind_result()`, `mysql_stmt_affected_rows()`, and so forth.

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_stmt_next_result()` to advance to the next result.

For an example that shows how to use `mysql_stmt_next_result()`, see [Section 22.8.16](#), “C API Support for Prepared `CALL` Statements”.

`mysql_stmt_next_result()` was added in MySQL 5.5.3.

Return Values

| Return Value | Description |
|--------------|--|
| 0 | Successful and there are more results |
| -1 | Successful and there are no more results |

| Return Value | Description |
|--------------|-------------------|
| >0 | An error occurred |

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

22.8.7.18. `mysql_stmt_num_rows()`

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

Description

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle. If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately. Otherwise, the row count is unavailable unless you count the rows as you fetch them.

`mysql_stmt_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_stmt_affected_rows()`.

Return Values

The number of rows in the result set.

Errors

None.

22.8.7.19. `mysql_stmt_param_count()`

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

Description

Returns the number of parameter markers present in the prepared statement.

Return Values

An unsigned long integer representing the number of parameters in a statement.

Errors

None.

Example

See the Example in [Section 22.8.7.10](#), “`mysql_stmt_execute()`”.

22.8.7.20. `mysql_stmt_param_metadata()`

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

Description

Return Values

Errors

22.8.7.21. `mysql_stmt_prepare()`

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *stmt_str, unsigned long length)
```

Description

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `stmt_str` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (“;”) or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (“?”) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are permitted in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not permitted for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 13.5.4](#), “Automatic Prepared Statement Repreparation”.

Return Values

Zero if the statement was prepared successfully. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC` [4030]

Commands were executed in an improper order.

- [CR_OUT_OF_MEMORY \[4030\]](#)

Out of memory.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns nonzero), the error message can be obtained by calling `mysql_stmt_error()`.

Example

See the Example in [Section 22.8.7.10](#), “`mysql_stmt_execute()`”.

22.8.7.22. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

Description

Resets a prepared statement on client and server to state after prepare. It resets the statement on the server, data sent using `mysql_stmt_send_long_data()`, unbuffered result sets and current errors. It does not clear bindings or stored result sets. Stored result sets will be cleared when executing the prepared statement (or closing it).

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

Return Values

Zero if the statement was reset successfully. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)

Commands were executed in an improper order.

- [CR_SERVER_GONE_ERROR \[4030\]](#)

The MySQL server has gone away.

- [CR_SERVER_LOST \[4030\]](#)

The connection to the server was lost during the query

- [CR_UNKNOWN_ERROR \[4029\]](#)

An unknown error occurred.

22.8.7.23. `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

Errors

- `CR_OUT_OF_MEMORY` [4030]
Out of memory.
- `CR_UNKNOWN_ERROR` [4029]
An unknown error occurred.

Example

See the Example in [Section 22.8.7.11](#), “`mysql_stmt_fetch()`”.

22.8.7.24. `mysql_stmt_row_seek()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQL_ROW_OFFSET offset)
```

Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

Errors

None.

22.8.7.25. `mysql_stmt_row_tell()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

22.8.7.26. `mysql_stmt_send_long_data()`

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int  
parameter_number, const char *data, unsigned long length)
```

Description

Enables an application to send parameter data to the server in pieces (or “chunks”). Call this function after `mysql_stmt_bind_param()` and before `mysql_stmt_execute()`. It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

**Note**

The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See [Section 22.8.7.22](#), “`mysql_stmt_reset()`”.

As of MySQL 5.5.11, the `max_long_data_size` [523] system variable controls the maximum size of parameter values that can be sent with `mysql_stmt_send_long_data()`. If this variable not set at server startup, the default is the value of the `max_allowed_packet` [519] system variable. `max_long_data_size` [523] is deprecated. In MySQL 5.6, it is removed and the maximum parameter size is controlled by `max_allowed_packet` [519].

Return Values

Zero if the data is sent successfully to server. Nonzero if an error occurred.

Errors

- `CR_INVALID_BUFFER_USE` [4032]

The parameter does not have a string or binary type.

- `CR_COMMANDS_OUT_OF_SYNC` [4030]

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR` [4030]

The MySQL server has gone away.

- `CR_OUT_OF_MEMORY` [4030]

Out of memory.

- `CR_UNKNOWN_ERROR` [4029]

An unknown error occurred.

Example

The following example demonstrates how to send the data for a `TEXT` column in chunks. It inserts the data value `'MySQL - The most popular Open Source database'` into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO \
                    test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long        length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
```

```

}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n param bind failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
    " - The most popular Open Source database",40))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

```

22.8.7.27. `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix C, Errors, Error Codes, and Common Problems](#).

Note that not all MySQL errors are yet mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

Return Values

A null-terminated character string containing the SQLSTATE error code.

22.8.7.28. `mysql_stmt_store_result()`

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

Description

Result sets are produced by calling `mysql_stmt_execute()` to executed prepared statements for SQL statements such as `SELECT`, `SHOW`, `DESCRIBE`, and `EXPLAIN`. By default, result sets for successfully executed prepared statements are not buffered on the client and `mysql_stmt_fetch()` fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call `mysql_stmt_store_result()` after binding data buffers with `mysql_stmt_bind_result()` and before calling `mysql_stmt_fetch()` to fetch rows. (For an example, see [Section 22.8.7.11](#), “`mysql_stmt_fetch()`”.)

`mysql_stmt_store_result()` is optional for result set processing, unless you will call `mysql_stmt_data_seek()`, `mysql_stmt_row_seek()`, or `mysql_stmt_row_tell()`. Those functions require a seekable result set.

It is unnecessary to call `mysql_stmt_store_result()` after executing an SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to [Section 22.8.7.23](#), “`mysql_stmt_result_metadata()`”.

Note

MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications don't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See [Section 22.8.7.3](#), “`mysql_stmt_attr_set()`”.

Return Values

Zero if the results are buffered successfully. Nonzero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC \[4030\]](#)
Commands were executed in an improper order.
- [CR_OUT_OF_MEMORY \[4030\]](#)
Out of memory.
- [CR_SERVER_GONE_ERROR \[4030\]](#)
The MySQL server has gone away.
- [CR_SERVER_LOST \[4030\]](#)
The connection to the server was lost during the query.
- [CR_UNKNOWN_ERROR \[4029\]](#)
An unknown error occurred.

22.8.8. C API Threaded Function Descriptions

To create a threaded client, use the functions described in the following sections. See also [Section 22.8.17.2, “How to Write a Threaded Client”](#).

22.8.8.1. `my_init()`

```
void my_init(void)
```

Description

`my_init()` initializes some global variables that MySQL needs. It also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program's use of the MySQL library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.

To access the prototype for `my_init()`, your program should include these header files:

```
#include <my_global.h>
#include <my_sys.h>
```

Return Values

None.

22.8.8.2. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` *is not invoked automatically by the client library*. It must be called explicitly to avoid a memory leak.

Return Values

None.

22.8.8.3. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

Description

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` is automatically called by `my_init()`, which itself is automatically called by `mysql_init()`, `mysql_library_init()`,

`mysql_server_init()`, and `mysql_connect()`. If you invoke any of those functions, `mysql_thread_init()` will be called for you.

Return Values

Zero if successful. Nonzero if an error occurred.

22.8.8.4. `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

Description

This function indicates whether the client library is compiled as thread-safe.

Return Values

1 if the client library is thread-safe, 0 otherwise.

22.8.9. C API Embedded Server Function Descriptions

MySQL applications can be written to use an embedded server. See [Section 22.7, “libmysqld, the Embedded MySQL Server Library”](#). To write such an application, you must link it against the `libmysqld` library by using the `-lmysqld` flag rather than linking it against the `libmysqlclient` client library by using the `-libmysqlclient` flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call `mysql_library_init()` to initialize the library and `mysql_library_end()` when you are done with it. See [Section 22.8.2, “C API Function Overview”](#).

22.8.9.1. `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

Description

This function initializes the MySQL library, which must be done before you call any other MySQL function. However, `mysql_server_init()` is deprecated and you should call `mysql_library_init()` instead. See [Section 22.8.3.40, “mysql_library_init\(\)”](#).

Return Values

Zero if successful. Nonzero if an error occurred.

22.8.9.2. `mysql_server_end()`

```
void mysql_server_end(void)
```

Description

This function finalizes the MySQL library, which should be done when you are done using the library. However, `mysql_server_end()` is deprecated and `mysql_library_end()` should be used instead. See [Section 22.8.3.39, “mysql_library_end\(\)”](#).

Return Values

None.

22.8.10. C API Client Plugin Functions

This section describes functions used for the client-side plugin API. They enable management of client plugins. For a description of the `st_mysql_client_plugin` structure used by these functions, see [Section 23.2.4.2.3, “Client Plugin Descriptors”](#).

It is unlikely that a client program needs to call the functions in this section. For example, a client that supports the use of authentication plugins normally causes a plugin to be loaded by calling `mysql_options()` to set the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options:

```
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

22.8.10.1. `mysql_client_find_plugin()`

```
struct st_mysql_client_plugin *mysql_client_find_plugin(MYSQL *mysql, const
char *name, int type)
```

Description

Returns a pointer to a loaded plugin, loading the plugin first if necessary. An error occurs if the type is invalid or the plugin cannot be found or loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `name`: The plugin name.
- `type`: The plugin type.

This function was added in MySQL 5.5.7.

Return Values

A pointer to the plugin for success. `NULL` if an error occurred.

Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 22.8.3.15, “mysql_error\(\)”](#), and [Section 22.8.3.14, “mysql_errno\(\)”](#).

Example

```
MYSQL mysql;
struct st_mysql_client_plugin *p;
```

```

if ((p = mysql_client_find_plugin(&mysql, "myplugin",
                                MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0)))
{
    printf("Plugin version: %d.%d.%d\n", p->version[0], p->version[1], p->version[2]);
}

```

22.8.10.2. `mysql_client_register_plugin()`

```

struct st_mysql_client_plugin *mysql_client_register_plugin(MYSQL *mysql,
struct st_mysql_client_plugin *plugin)

```

Description

Adds a plugin structure to the list of loaded plugins. An error occurs if the plugin is already loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `plugin`: A pointer to the plugin structure.

This function was added in MySQL 5.5.7.

Return Values

A pointer to the plugin for success. `NULL` if an error occurred.

Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 22.8.3.15](#), “`mysql_error()`”, and [Section 22.8.3.14](#), “`mysql_errno()`”.

22.8.10.3. `mysql_load_plugin()`

```

struct st_mysql_client_plugin *mysql_load_plugin(MYSQL *mysql, const char
*name, int type, int argc, ...)

```

Description

Loads a MySQL client plugin, specified by name and type. An error occurs if the type is invalid or the plugin cannot be loaded.

It is not possible to load multiple plugins of the same type. An error occurs if you try to load a plugin of a type already loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `name`: The name of the plugin to load.
- `type`: The type of plugin to load, or `-1` to disable type checking. If type is not `-1`, only plugins matching the type are considered for loading.

- `argc`: The number of following arguments (0 if there are none). Interpretation of any following arguments depends on the plugin type.

This function was added in MySQL 5.5.7.

Another way to cause plugins to be loaded is to set the `LIBMYSQL_PLUGINS` environment variable to a semicolon-separated list of plugin names. For example:

```
shell> export LIBMYSQL_PLUGINS="myplugin1;myplugin2"
```

Plugins named by `LIBMYSQL_PLUGINS` are loaded when the client program calls `mysql_library_init()`. No error is reported if problems occur loading these plugins.

Return Values

A pointer to the plugin if it was loaded successfully. `NULL` if an error occurred.

Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 22.8.3.15](#), “`mysql_error()`”, and [Section 22.8.3.14](#), “`mysql_errno()`”.

Example

```
MYSQL mysql;

if(!mysql_load_plugin(&mysql, "myplugin",
                     MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0))
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
    exit(-1);
}
```

See Also

See also [Section 22.8.10.3](#), “`mysql_load_plugin()`”, [Section 22.8.3.15](#), “`mysql_error()`”, [Section 22.8.3.14](#), “`mysql_errno()`”.

22.8.10.4. `mysql_load_plugin_v()`

```
struct st_mysql_client_plugin *mysql_load_plugin_v(MYSQL *mysql, const char
*name, int type, int argc, va_list args)
```

Description

This function is equivalent to `mysql_load_plugin()`, but it accepts a `va_list` instead of a variable list of parameters.

This function was added in MySQL 5.5.7.

See Also

See also [Section 22.8.10.3](#), “`mysql_load_plugin()`”.

22.8.10.5. `mysql_plugin_options()`

```
int mysql_plugin_options(struct st_mysql_client_plugin *plugin, const char
*option, const void *value)
```

Description

Passes an option type and value to a plugin. This function can be called multiple times to set several options. If the plugin does not have an option handler, an error occurs.

Specify the parameters as follows:

- `plugin`: A pointer to the plugin structure.
- `option`: The option to be set.
- `value`: A pointer to the option value.

This function was added in MySQL 5.5.7.

Return Values

Zero for success, 1 if an error occurred. If the plugin has an option handler, that handler should also return zero for success and 1 if an error occurred.

22.8.11. Common Questions and Problems When Using the C API

22.8.11.1. Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return `NULL` following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data could not be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a nonempty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a nonzero value, the statement should have produced a nonempty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

22.8.11.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.

For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With

`mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.

- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See [Section 22.8.3.37](#), “`mysql_insert_id()`”.
- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

22.8.11.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

When inserting multiple values, the last automatically incremented value is returned.

For `LAST_INSERT_ID()` [1194], the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a nonmagic value (that is, a value that is not `NULL` and not `0`). Using `LAST_INSERT_ID()` [1194] and `AUTO_INCREMENT` columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement *that* client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
VALUES(NULL,'text');           # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` [1194] returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()` [1194].

For more information on obtaining the last ID in an `AUTO_INCREMENT` column:

- For information on `LAST_INSERT_ID()` [1194], which can be used within an SQL statement, see [Section 12.14](#), “Information Functions”.
- For information on `mysql_insert_id()`, the function you use from within the C API, see [Section 22.8.3.37](#), “`mysql_insert_id()`”.

- For information on obtaining the auto-incremented value when using Connector/J, see [Section 22.3.6.4, “Retrieving `AUTO_INCREMENT` Column Values through JDBC”](#).
- For information on obtaining the auto-incremented value when using Connector/ODBC, see [Section 22.1.7.1.1, “Obtaining Auto-Increment Values”](#).

22.8.12. Controlling Automatic Reconnection Behavior

The MySQL client library can perform an automatic reconnection to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. In this case, the library tries once to reconnect to the server and send the statement again.

In MySQL 5.5, auto-reconnect is disabled by default.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure that auto-reconnect is disabled. To ensure this, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option:

```
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

If the connection has gone down, the effect of `mysql_ping()` depends on the auto-reconnect state. If auto-reconnect is enabled, `mysql_ping()` performs a reconnect. Otherwise, it returns an error.

Some client programs might provide the capability of controlling automatic reconnection. For example, `mysql` reconnects by default, but the `--skip-reconnect` [281] option can be used to suppress this behavior.

If an automatic reconnection does occur (for example, as a result of calling `mysql_ping()`), there is no explicit indication of it. To check for reconnection, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset on the server side and your application will not know about it. The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.
- All `TEMPORARY` tables are closed (and dropped).
- Session variables are reinitialized to the values of the corresponding variables. This also affects variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `HANDLER` variables are closed.
- The value of `LAST_INSERT_ID()` [1194] is reset to 0.
- Locks acquired with `GET_LOCK()` [1199] are released.

If the connection drops, it is possible that the session associated with the connection on the server side will still be running if the server has not yet detected that the client is no longer connected. In this case,

any locks held by the original connection still belong to that session, so you may want to kill it by calling `mysql_kill()`.

22.8.13. C API Support for Multiple Statement Execution

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for `SELECT`) or an affected-rows count (as for `INSERT`, `UPDATE`, and so forth).

MySQL 5.5 also supports the execution of a string containing multiple statements separated by semicolon (“;”) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. *Failure to process the result this way may result in a dropped connection to the server.*

Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.

In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.

- The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement. See [Section 22.8.4, “C API Prepared Statements”](#).

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:
 - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option *must* be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error `Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context`. As of MySQL 5.5.3, `CLIENT_MULTI_RESULTS` is enabled by default.
 - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS` |

`CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.

- After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is *not* sufficient to permit processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.
2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.
3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.
4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.

One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns nonzero. The code as written distinguishes between no more results and an error, which enables a message to be printed for the latter occurrence.

```

/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
    db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL)
{
    printf("mysql_real_connect() failed\n");
    mysql_close(mysql);
    exit(1);
}

/* execute multiple statements */
status = mysql_query(mysql,
    "DROP TABLE IF EXISTS test_table;\
    CREATE TABLE test_table(id INT);\
    INSERT INTO test_table VALUES(10);\
    UPDATE test_table SET id=20 WHERE id=10;\
    SELECT * FROM test_table;\
    DROP TABLE test_table");

if (status)
{
    printf("Could not execute statement(s)");
    mysql_close(mysql);
    exit(0);
}

/* process each statement result */
do {
    /* did current statement return data? */
    result = mysql_store_result(mysql);
    if (result)
    {
        /* yes; process rows and free the result set */
        process_result_set(mysql, result);
    }
} while (mysql_next_result());

```

```

mysql_free_result(result);
}
else /* no result set or error */
{
    if (mysql_field_count(mysql) == 0)
    {
        printf("%lld rows affected\n",
            mysql_affected_rows(mysql));
    }
    else /* some error occurred */
    {
        printf("Could not retrieve result set\n");
        break;
    }
}
/* more results? -1 = no, >0 = error, 0 = yes (keep looping) */
if ((status = mysql_next_result(mysql)) > 0)
    printf("Could not execute statement\n");
} while (status == 0);

mysql_close(mysql);

```

22.8.14. C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

- [TIME](#), [TIMESTAMP](#), and [DATETIME](#) do not support parts of seconds (for example, from [DATE_FORMAT\(\)](#) [1138]).
- When converting an integer to string, [ZEROFILL](#) is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with [MIN\(number-with-zerofill\)](#) [1206]).
- When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.
- Prepared statements use the query cache under the conditions described in [Section 8.9.3.1, "How the Query Cache Operates"](#).
- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by ";" characters).
- Before MySQL 5.5.3, prepared [CALL](#) statements cannot invoke stored procedures that return result sets because prepared statements do not support multiple result sets. Nor can the calling application access a stored procedure's [OUT](#) or [INOUT](#) parameters when the procedure returns. As of MySQL 5.5.3, these capabilities are supported as described in [Section 22.8.16, "C API Support for Prepared CALL Statements"](#).

22.8.15. C API Prepared Statement Handling of Date and Time Values

The binary (prepared statement) protocol enables you to send and receive date and time values ([DATE](#), [TIME](#), [DATETIME](#), and [TIMESTAMP](#)), using the [MYSQL_TIME](#) structure. The members of this structure are described in [Section 22.8.5, "C API Prepared Statement Data Structures"](#).

To send temporal data values, create a prepared statement using [mysql_stmt_prepare\(\)](#). Then, before calling [mysql_stmt_execute\(\)](#) to execute the statement, use the following procedure to set up each temporal parameter:

1. In the [MYSQL_BIND](#) structure associated with the data value, set the [buffer_type](#) member to the type that indicates what kind of temporal value you're sending. For [DATE](#), [TIME](#), [DATETIME](#),

or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.

2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.
3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to be passed.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_stmt_bind_result()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```

MYSQL_TIME  ts;
MYSQL_BIND  bind[3];
MYSQL_STMT  *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \
                timestamp_field) VALUES(?,?,?");

22.8.16. C API Support for Prepared `CALL` Statements

This section describes prepared-statement support in the C API for stored procedures executed using `CALL` statements:

Prior to MySQL 5.5.3, prepared `CALL` statements can be used only for stored procedures that produce at most one result set. Nor can the calling application use placeholders for `OUT` or `INOUT` parameters.

MySQL 5.5.3 expands support for stored procedures executed using prepared `CALL` statements in the following ways:

- A stored procedure can produce any number of result sets. The number of columns and the data types of the columns need not be the same for all result sets.
- The final values of `OUT` and `INOUT` parameters are available to the calling application after the procedure returns. These parameters are returned as an extra single-row result set following any result sets produced by the procedure itself. The row contains the values of the `OUT` and `INOUT` parameters in the order in which they are declared in the procedure parameter list.

The following discussion shows how to use these capabilities through the C API for prepared statements. To use prepared `CALL` statements through the `PREPARE` and `EXECUTE` statements, see [Section 13.2.1, “CALL Syntax”](#).

If an application might be compiled or executed in a context where a version of MySQL older than 5.5.3 is used, prepared `CALL` capabilities for multiple result sets and `OUT` or `INOUT` parameters might not be available:

- For the client side, the application will not compile unless the libraries are from MySQL 5.5.3 or higher (the API function and symbols introduced in that version will not be present).
- To verify at runtime that the server is recent enough, a client can use this test:

```
if (mysql_get_server_version(mysql) < 50503)
{
    fprintf(stderr,
           "Server does not support required CALL capabilities\n");
    mysql_close(mysql);
    exit (1);
}
```

An application that executes a prepared `CALL` statement should use a loop that fetches a result and then invokes `mysql_stmt_next_result()` to determine whether there are more results. The results consist of any result sets produced by the stored procedure followed by a final status value that indicates whether the procedure terminated successfully.

If the procedure has `OUT` or `INOUT` parameters, the result set preceding the final status value contains their values. To determine whether a result set contains parameter values, test whether the `SERVER_PS_OUT_PARAMS` bit is set in the `server_status` member of the `MYSQL` connection handler:

```
mysql->server_status & SERVER_PS_OUT_PARAMS
```

The following example uses a prepared `CALL` statement to execute a stored procedure that produces multiple result sets and that provides parameter values back to the caller by means of `OUT` and `INOUT` parameters. The procedure takes parameters of all three types (`IN`, `OUT`, `INOUT`), displays their initial values, assigns new values, displays the updated values, and returns. The expected return information from the procedure therefore consists of multiple result sets and a final status:

- One result set from a `SELECT` that displays the initial parameter values: `10, NULL, 30`. (The `OUT` parameter is assigned a value by the caller, but this assignment is expected to be ineffective: `OUT` parameters are seen as `NULL` within a procedure until assigned a value within the procedure.)

- One result set from a `SELECT` that displays the modified parameter values: 100, 200, 300.
- One result set containing the final `OUT` and `INOUT` parameter values: 200, 300.
- A final status packet.

The code to execute the procedure:

```
MYSQL_STMT *stmt;
MYSQL_BIND ps_params[3]; /* input parameter buffers */
int int_data[3]; /* input/output values */
my_bool is_null[3]; /* output value nullability */
int status;

/* set up stored procedure */
status = mysql_query(mysql, "DROP PROCEDURE IF EXISTS p1");
test_error(mysql, status);

status = mysql_query(mysql,
    "CREATE PROCEDURE p1("
    " IN p_in INT, "
    " OUT p_out INT, "
    " INOUT p_inout INT) "
    "BEGIN "
    " SELECT p_in, p_out, p_inout; "
    " SET p_in = 100, p_out = 200, p_inout = 300; "
    " SELECT p_in, p_out, p_inout; "
    "END");
test_error(mysql, status);

/* initialize and prepare CALL statement with parameter placeholders */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    printf("Could not initialize statement\n");
    exit(1);
}
status = mysql_stmt_prepare(stmt, "CALL p1(?, ?, ?)", 16);
test_stmt_error(stmt, status);

/* initialize parameters: p_in, p_out, p_inout (all INT) */
memset(ps_params, 0, sizeof (ps_params));

ps_params[0].buffer_type = MYSQL_TYPE_LONG;
ps_params[0].buffer = (char *) &int_data[0];
ps_params[0].length = 0;
ps_params[0].is_null = 0;

ps_params[1].buffer_type = MYSQL_TYPE_LONG;
ps_params[1].buffer = (char *) &int_data[1];
ps_params[1].length = 0;
ps_params[1].is_null = 0;

ps_params[2].buffer_type = MYSQL_TYPE_LONG;
ps_params[2].buffer = (char *) &int_data[2];
ps_params[2].length = 0;
ps_params[2].is_null = 0;

/* bind parameters */
status = mysql_stmt_bind_param(stmt, ps_params);
test_stmt_error(stmt, status);

/* assign values to parameters and execute statement */
int_data[0]= 10; /* p_in */
int_data[1]= 20; /* p_out */
int_data[2]= 30; /* p_inout */
```

```
status = mysql_stmt_execute(stmt);
test_stmt_error(stmt, status);

/* process results until there are no more */
do {
    int i;
    int num_fields;          /* number of columns in result */
    MYSQL_FIELD *fields;    /* for result set metadata */
    MYSQL_BIND *rs_bind;   /* for output buffers */

    /* the column count is > 0 if there is a result set */
    /* 0 if the result is only the final status packet */
    num_fields = mysql_stmt_field_count(stmt);

    if (num_fields > 0)
    {
        /* there is a result set to fetch */
        printf("Number of columns in result: %d\n", (int) num_fields);

        /* what kind of result set is this? */
        printf("Data: ");
        if(mysql->server_status & SERVER_PS_OUT_PARAMS)
            printf("this result set contains OUT/INOUT parameters\n");
        else
            printf("this result set is produced by the procedure\n");

        MYSQL_RES *rs_metadata = mysql_stmt_result_metadata(stmt);
        test_stmt_error(stmt, rs_metadata == NULL);

        fields = mysql_fetch_fields(rs_metadata);

        rs_bind = (MYSQL_BIND *) malloc(sizeof (MYSQL_BIND) * num_fields);
        if (!rs_bind)
        {
            printf("Cannot allocate output buffers\n");
            exit(1);
        }
        memset(rs_bind, 0, sizeof (MYSQL_BIND) * num_fields);

        /* set up and bind result set output buffers */
        for (i = 0; i < num_fields; ++i)
        {
            rs_bind[i].buffer_type = fields[i].type;
            rs_bind[i].is_null = &is_null[i];

            switch (fields[i].type)
            {
                case MYSQL_TYPE_LONG:
                    rs_bind[i].buffer = (char *) &(int_data[i]);
                    rs_bind[i].buffer_length = sizeof (int_data);
                    break;

                default:
                    fprintf(stderr, "ERROR: unexpected type: %d.\n", fields[i].type);
                    exit(1);
            }
        }
    }

    status = mysql_stmt_bind_result(stmt, rs_bind);
    test_stmt_error(stmt, status);

    /* fetch and display result set rows */
    while (1)
    {
        status = mysql_stmt_fetch(stmt);

        if (status == 1 || status == MYSQL_NO_DATA)
```

```

        break;

    for (i = 0; i < num_fields; ++i)
    {
        switch (rs_bind[i].buffer_type)
        {
            case MYSQL_TYPE_LONG:
                if (*rs_bind[i].is_null)
                    printf(" val[%d] = NULL;", i);
                else
                    printf(" val[%d] = %ld;",
                            i, (long) *((int *) rs_bind[i].buffer));
                break;

            default:
                printf(" unexpected type (%d)\n",
                        rs_bind[i].buffer_type);
        }
    }
    printf("\n");
}

mysql_free_result(rs_metadata); /* free metadata */
free(rs_bind);                /* free output buffers */
}
else
{
    /* no columns = final status packet */
    printf("End of procedure output\n");
}

/* more results? -1 = no, >0 = error, 0 = yes (keep looking) */
status = mysql_stmt_next_result(stmt);
if (status > 0)
    test_stmt_error(stmt, status);
} while (status == 0);

mysql_stmt_close(stmt);

```

Execution of the procedure should produce the following output:

```

Number of columns in result: 3
Data: this result set is produced by the procedure
  val[0] = 10; val[1] = NULL; val[2] = 30;
Number of columns in result: 3
Data: this result set is produced by the procedure
  val[0] = 100; val[1] = 200; val[2] = 300;
Number of columns in result: 2
Data: this result set contains OUT/INOUT parameters
  val[0] = 200; val[1] = 300;
End of procedure output

```

The code uses two utility routines, `test_error()` `test_stmt_error()`, to check for errors and terminate after printing diagnostic information if an error occurred:

```

static void test_error(MYSQL *mysql, int status)
{
    if (status)
    {
        fprintf(stderr, "Error: %s (errno: %d)\n",
                mysql_error(mysql), mysql_errno(mysql));
        exit(1);
    }
}

static void test_stmt_error(MYSQL_STMT *stmt, int status)
{

```

```

if (status)
{
    fprintf(stderr, "Error: %s (errno: %d)\n",
            mysql_stmt_error(stmt), mysql_stmt_errno(stmt));
    exit(1);
}
}

```

22.8.17. Building Client Programs

If you compile MySQL clients that you've written yourself or that you obtain from a third-party, they must be linked using the `-lmysqlclient -lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use `-L/usr/local/mysql/lib -lmysqlclient -lz` in the link command.

For clients that use MySQL header files, you may need to specify an `-I` option when you compile them (for example, `-I/usr/local/mysql/include`), so that the compiler can find the header files.

Compiling MySQL Clients on Unix

To make it simpler to compile MySQL programs on Unix, we have provided the `mysql_config` script for you. See [Section 4.7.2, “mysql_config — Get Compile Options for Compiling Clients”](#).

You can use it to compile a MySQL client as follows:

```

CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"

```

The `sh -c` is needed to get the shell not to treat the output from `mysql_config` as one word.

Compiling MySQL Clients on Microsoft Windows

On Windows, you can link your code with either the dynamic or static client library. The static library is named `mysqlclient` and the dynamic library is named `libmysql`.

If you link with the static library, failure can occur if certain conditions are not satisfied:

- The client application must be compiled with exactly the same version of Visual Studio as that used to compile the library.
- The client application should link the C runtime statically by using the `/MT` compiler option.

If the client application is built in in debug mode and uses the static debug C runtime (`/MTd` compiler option), it can link the `mysqlclient` if that library was built using the same option. If the client application uses the dynamic C runtime (`/MD` option, or `/MDd` option in debug mode), it cannot link with the static client library and must use the dynamic library.

The MSDN page describing the link options can be found here: <http://msdn.microsoft.com/en-us/library/2kzt1wy3.aspx>

22.8.17.1. Problems Linking to the MySQL Client Library

When linking with the C API, the following errors may occur on some systems:

```

gcc -g -o client test.o -L/usr/local/lib/mysql \
    -lmysqlclient -lsocket -lnsl
Undefined      first referenced

```

```

symbol      in file
floor      /usr/local/lib/mysql/libmysqlclient.a(password.o)
ld: fatal: Symbol referencing errors. No output written to client

```

If this happens on your system, you must include the math library by adding `-lm` to the end of the compile/link line.

When you are linking an application program to use the MySQL client library, you might get undefined reference errors for symbols that start with `mysql_`, such as those shown here:

```

/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
/tmp/ccFKsdPa.o(.text+0x31): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x57): undefined reference to `mysql_real_connect'
